## HIGHLIGHTS

- The catalytic performance of C<sub>2</sub>H<sub>2</sub> semi-hydrogenation on the Pd@M catalysts strongly depends on the shell Pd ensemble form.
- Pd<sub>7</sub>@M with the Pd ensemble of dimer and trimer exhibits the best catalytic performance toward C<sub>2</sub>H<sub>4</sub> formation.
- The activity and selectivity of C<sub>2</sub>H<sub>4</sub> formation has a volcano curve relationship with the *d*-band center of Pd@M catalysts.
- Pd<sub>7</sub>@M catalysts with the best catalytic performance are attributed to the moderate *d*-band center.

## ABSTRACT

To reveal the influence of shell Pd ensemble form in the core-shell Pd@M (M = Cu, Ag, Au) catalysts on the catalytic performance of C<sub>2</sub>H<sub>2</sub> semi-hydrogenation, the mechanism of C<sub>2</sub>H<sub>2</sub> semi-hydrogenation on Pd@M catalysts with different shell Pd ensemble are fully investigated using DFT and microkinetic modeling calculations. The results show that C<sub>2</sub>H<sub>4</sub> selectivity and its formation activity closely depend on the shell Pd ensemble form; among Pd@Cu with different shell Pd ensemble, C<sub>2</sub>H<sub>4</sub> selectivity and its formation activity has a volcano curve relationship with the *d*-band center of Pd@Cu, in which Pd<sub>7</sub>@Cu with the shell Pd ensemble of dimer and trimer is the best due to the moderate *d*-band center. The same things also occur on the Pd@Ag and Pd@Au. It is proposed that controlling the ensemble form of shell noble-metal Pd may be a good way to adjust the catalytic performance toward the selective hydrogenation of other alkynes.

## 1. Introduction

One of the important chemical method to remove trace  $C_2H_2$  impurities in  $C_2H_4$  raw materials produced by petroleum pyrolysis is  $C_2H_2$  semi-hydrogenation (Yang et al., 2012; Zhang et al., 2016). Pd catalyst has been widely employed in  $C_2H_2$  semi-hydrogenation due to its excellent activity (Khan et al., 2006; Ngamsom et al., 2004). However, the high cost and the poor  $C_2H_4$  selectivity limit its industrial application (Osswald et al., 2008). In order to solve these issues, the transition metals Au (Sárkány et al., 2008; Sárkány et al., 2002), Ag (Pei et al., 2015; Lee et al., 2011); or Cu (Leviness et al., 1984; Guczi et al., 1999) doped into Pd catalysts were used to improve  $C_2H_4$  selectivity. Meanwhile, the metal Pd doped into the substrate Cu, Ag and Au to form PdCu (Leviness et al., 1984; Friedrich et al., 2013; McCue et al., 2014); PdAg (Pei et al., 2015; Meng and Wang, 2014; Liu, 2016; Komeili et al., 2015); and PdAu (Zhang et al., 2014) alloy catalysts are also studied for  $C_2H_2$  semi-hydrogenation due to its better catalytic performance toward  $C_2H_4$  formation, for instance, the experiments (McCue et al., 2014) showed that Pd-doped Cu/Al<sub>2</sub>O<sub>3</sub> catalysts with Cu:Pd ratio of 50:1 exhibits 80%  $C_2H_4$  selectivity and 90%  $C_2H_2$  conversion at 363 K. Leviness et al. (Leviness et al., 1984) showed that the decreasing of surface Pd content on PdCu/Al<sub>2</sub>O<sub>3</sub> at elevated temperature leads to an increase of  $C_2H_4$  selectivity in  $C_2H_2$  hydrogenation. Further, the Ag-based and Au-based catalysts were also investigated, for example, the experiments (Pei et al., 2015) indicated that the simultaneous high  $C_2H_2$  conversion and  $C_2H_4$  selectivity were attained over the single-atom Pd doped Ag alloy catalysts. Compared to Pd catalyst, Zhang et al. (Zhang et al., 2014) showed that both Ag-Pd and Au-Pd supported by SiO<sub>2</sub> increase  $C_2H_4$  selectivity.

Nowadays, the core-shell catalysts presented the excellent catalytic performance due to their unique structures (McCue et al., 2014; Feng et al., 2018; Tedsree et al., 2011); for example, He et al. (He et al., 2016) demonstrated that the core-shell Cu<sub>1</sub>Pd<sub>3</sub>@Pd catalyst enhanced HCOOH dissociation activity with better durability compared to Pd catalyst. The experiments (Ren et al., 2014) found that Cu@Pd/C with a Cu:Pd atomic ratio of 27:73 has the highest activity of HCOOH oxidation. Takht et al. (Takht et al., 2014) experimentally synthesized the core-shell Pd-Ag/ $\alpha$ -Al<sub>2</sub>O<sub>3</sub>, in which Pd loaded as a shell layer of 20–30  $\mu$ m thickness has 100%  $C_2H_4$  selectivity. Sárkány et al. (Sárkány et al., 2008) synthesized Pd<sub>shell</sub>-Au<sub>core</sub>/SiO<sub>2</sub> with various thicknesses of Pd shell, the 68–80% Pd homogenized particle on Au core exhibits superior catalytic activity and selectivity for the hydrogenation reaction. Wang et al. (Wang et al., 2013) found that Au@Pd/N-mrGO shows better HCOOH dissociation activity to produce H<sub>2</sub> in comparison with its alloy or monometallic counterparts at room temperature. Thus, the core-shell Pd@M (M = Cu, Ag, Au) catalysts exhibit excellent performance toward some targeted reactions.

Further, the shell metal ensemble of core-shell alloy catalysts has significant influence on their catalytic performance; for example, Wang et al. (Wang et al., 2020) showed that Pd trimer of PdAg catalysts were prospective for  $C_2H_2$  semi-hydrogenation. Ma et al. (Ma et al., 2017) theoretically indicated that 0.01 ML Pd on Pd/Cu (111) surface exhibited better  $C_2H_4$  selectivity and its formation activity than 1.00 ML Pd in  $C_2H_2$  semi-hydrogenation. Choi et al. (Choi et al., 2019) demonstrated that the best activity of HCOOH dissociation into H<sub>2</sub> was obtained on Pd@PdAg catalysts, in which PdAg alloy cores has an average Pd/Ag atomic ratio of 3.5:1 and Pd shells with 1.1 atomic layers. Zhang et al. (Zhang et al., 2018) found that Pd-modified Cu catalysts with Pd ensemble consisted of one surface and its connected subsurface Pd atoms enhance  $C_2H_4$  selectivity and its formation activity, which is attributed to the electronic properties change of the catalyst surface. Duan et al. (Duan

et al., 2016) showed that Pt<sub>ML</sub>@Au(111) is highly active and selective toward HCOOH oxidation, which effectively inhibit the formation of poisonous species CO. Wang et al. (Wang et al., 2019) theoretically revealed that Pd@Au catalysts with the shell Pd dimer achieve the highest activity of CO<sub>2</sub> reduction. Experimental and theoretical studies by Lee et al. (Lee et al., 2016) demonstrated that Pd@Au with the shell Pd trimer exhibited the excellent catalytic performance in HCOOH dehydrogenation. Yang et al. (Yang et al., 2019) elucidated that Pd dimer has the best activity of CO oxidation at low temperature, while the tetramer outperforms the other forms at high temperature. These reported studies showed that the core-shell catalyst with the special shell metal ensemble can exhibit the excellent catalytic performance. However, up to now, to the best of our knowledge, for the core-shell Pd<sub>shell</sub>@M<sub>core</sub> (M = Cu, Ag, Au) alloy catalysts denoted as Pd@M in this study, a fundamental understanding about the influences of the shell Pd ensemble form on  $C_2H_4$  selectivity and its formation activity in  $C_2H_2$  semi-hydrogenation is still ambiguous, which is of very significance to design the newly-efficient core-shell Pd@M catalyst in  $C_2H_2$  semi-hydrogenation.

In this study, the core-shell Pd@M (M = Cu, Ag, Au) catalysts with different forms of shell Pd ensemble are designed to elucidate the influence of the shell Pd ensemble form on  $C_2H_4$  selectivity and its formation activity in  $C_2H_2$  semi-hydrogenation, the density functional theory (DFT) and microkinetic modeling calculations are used to probe into the underlying mechanism of  $C_2H_2$  semi-hydrogenation on Pd@M catalysts. Further, the electronic properties are analyzed to reveal the microscopic essences. The results are expected to deepen the understanding about the influence of shell noble metal ensemble form in the core-shell catalysts on  $C_2H_4$  selectivity and its formation activity in  $C_2H_2$  semi-hydrogenation, and give out a valuable structure clue to design the high-efficiency core-shell catalysts that are consisted of the shell noble metal-doped into the core non-noble metal.

## 2. Computational details

### 2.1. Computational method

Dmol<sup>3</sup> program package of Materials Studio 8.0 were employed in all calculations in this study (Delley, 2000; Delley, 1990). Generalized gradient approximation (GGA) with the exchange–correlation functional Perdew–Burke–Ernzerhof (PBE) was implemented to calculate the electronic structure (Delley, 1996; Tian et al., 2007). The energy, maximum force and maximum displacement convergence criteria correspond to the values of  $2.0 \times 10^{-5}$  Ha,  $4.0 \times 10^{-3}$  Ha/Å and  $5.0 \times 10^{-3}$  Å, respectively. The cutoff values of Pd, Cu, Ag and Au elements were 4.0 Å. The smearing width was 0.005 Ha. The H and C<sub>2</sub>H<sub>x</sub> species were treated using all electron basis set; the Cu and Pd atoms were treated using the effective core potential (ECP) (Dolg et al., 1987). A double-valued base plus polarization function (DNP) was used to treat the valence electron wave function (Zhou et al., 2007). The Brillouin zone *k*-point was selected as (2 × 2 × 1). The Complete LST/QST method was used to search transition state (Halgren and Lipscomb, 1977; Govind et al., 2003; Paul and Sautet, 1994), and confirmed by the TS Confirmation and frequency analysis.

Previous studies revealed that the high ratio of H<sub>2</sub>/C<sub>2</sub>H<sub>2</sub> and the high temperature promote  $C_2H_2$  hydrogenation instead of its polymerization (Wehrli et al., 1991; Ahn et al., 2007; Battiston et al., 1982), meanwhile,  $C_2H_2$  semi-hydrogenation usually happens at the temperature 300–500 K, thus, the temperature 425 K was considered for the energy calculations (the details are presented in the Supplementary Material).

## 2.2. Computational models

Previous experiments (Ren et al., 2014; Lu et al., 2012) demonstrated that Pd@Cu particle exhibited a narrow size range between 1.9 and 4.5 nm, and the (111) surfaces of Pd and Pd@Cu were detected by XRD pattern (Ren et al., 2014), indicating that the shell surface structure around the reactive site is similar to the periodic model, so the periodic model can be used to simulate the structural characteristics of large particles. Further, theoretical studies by He et al. (He et al., 2016) constructed Cu<sub>1</sub>@Pd<sub>3</sub>(111) periodic model to model the core-shell catalysts, and the same kinds of core-shell catalysts are also used by Yuan et al. (Yuan and Liu, 2013) and Cho et al. (Cho et al., 2017). Thus, the periodic model of M and Pd@M (M = Cu, Ag, Au) catalysts employed to present the core-shell catalysts in this study is reasonable.

For the pure metal M (M = Cu, Ag, Au) catalysts, the flat (111) surface is the mostly exposed and the most stable for the face centered cubic metal M (Eren et al., 2016; Brandt et al., 2009; Meier and Castellani, 2017), the M(111) surface with a four-layer *p* (4 × 4) unit cell is usually to model the pure metal M catalyst; the bottom one layer is fixed with the other fragments relaxed. A vacuum of 15 Å is considered to eliminate the layer-to-layer unphysical interaction between surface slabs due to the periodic images. The reliability of *p*(4 × 4) unit cell is also confirmed, as presented in the Supplementary Material.

Aiming at revealing the influence of shell Pd ensemble form on C<sub>2</sub>H<sub>4</sub> selectivity and its formation activity in C<sub>2</sub>H<sub>2</sub> semi-hydrogenation, the core-shell Pd@M (M = Cu, Ag, Au) catalysts with different forms of shell Pd ensemble are constructed with the replacement of 1, 2, 3, 7, 8 and a monolayer (16) M atoms by the corresponding number of Pd atoms, denoted as Pd<sub>1</sub>@M, Pd<sub>2</sub>@M, Pd<sub>3</sub>@M, Pd<sub>7</sub>@M, Pd<sub>8</sub>@M and Pd<sub>ML</sub>@M, as shown in Fig. 1. Previous studies reported that these models were reliable to model different forms of shell Pd ensemble in the core-shell catalysts (Wang et al., 2019; Lee et al., 2016; Yang et al., 2019), in which the Pd<sub>1</sub>@M, Pd<sub>2</sub>@M and Pd<sub>3</sub>@M catalysts are established to model the single-atom Pd, Pd dimer and Pd trimer. Moreover, previous studies by Wang et al. (Wang et al., 2020) also showed that Pd<sub>7</sub>@M and Pd<sub>8</sub>@M catalysts are established on the basis of Pd dimer and Pd trimer. Meanwhile, the experiments (Wang et al., 2019) have synthesized Pd@Au catalysts with various Pd dispersions by low temperature reduction of a palladium salt with hydrogen, in which the decoration of Au nanoparticles with Pd atoms can be obtained by precisely controlling the doses and varying the average size of Pd ensembles on the bimetallic surfaces. Similarly,

the specific Pd shell ensemble catalyst used in this study could be prepared by the experiments.

## 3. Results and discussion

### 3.1. Reaction pathway of C<sub>2</sub>H<sub>2</sub> semi-hydrogenation

The possible hydrogenation process in C<sub>2</sub>H<sub>2</sub> semi-hydrogenation is described in Fig. 2 with three paths. The desired C<sub>2</sub>H<sub>4</sub> desorption path to gas phase C<sub>2</sub>H<sub>4</sub> is C<sub>2</sub>H<sub>2</sub>(ad) + H(ad) → C<sub>2</sub>H<sub>3</sub>(ad) + H(ad) → C<sub>2</sub>H<sub>4</sub>(ad) → C<sub>2</sub>H<sub>4</sub>(g); C<sub>2</sub>H<sub>4</sub> hydrogenation path to ethane is C<sub>2</sub>H<sub>2</sub>(ad) + H(ad) → C<sub>2</sub>H<sub>3</sub>(ad) + H(ad) → C<sub>2</sub>H<sub>4</sub>(ad) + 2H(ad) → C<sub>2</sub>H<sub>6</sub>(g); CHCH<sub>3</sub> hydrogenation path to ethane is C<sub>2</sub>H<sub>2</sub>(ad) + H(ad) → C<sub>2</sub>H<sub>3</sub>(ad) + H(ad) → CHCH<sub>3</sub>(ad) + 2H(ad) → C<sub>2</sub>H<sub>6</sub>(g). On the other hand, the polymerization process to produce 1,3-butadiene as the green oil precursor also includes three paths: the first is C<sub>2</sub>H<sub>2</sub>(ad) + C<sub>2</sub>H<sub>2</sub>(ad) → C<sub>4</sub>H<sub>4</sub>(ad); the second is C<sub>2</sub>H<sub>2</sub>(ad) + C<sub>2</sub>H<sub>3</sub>(ad) → C<sub>4</sub>H<sub>5</sub>(ad); the third is C<sub>2</sub>H<sub>3</sub>(ad) + C<sub>2</sub>H<sub>3</sub>(ad) → C<sub>4</sub>H<sub>6</sub>(ad).

Aiming at obtaining the dominant path of the hydrogenation process on the Pd@M (M = Cu, Ag, Au) catalysts, firstly, the priority between C<sub>2</sub>H<sub>4</sub> desorption and its hydrogenation needs to be judged, if it is true, C<sub>2</sub>H<sub>4</sub> desorption path is favored instead of C<sub>2</sub>H<sub>4</sub> hydrogenation path; Then, to confirm whether C<sub>2</sub>H<sub>4</sub> desorption path is also dominant compared to CHCH<sub>3</sub> hydrogenation path, if it is true, C<sub>2</sub>H<sub>4</sub> desorption path is the dominant path among three paths in the hydrogenation process. Further, the polymerization process to form 1,3-butadiene is examined on the catalysts with C<sub>2</sub>H<sub>4</sub> desorption path as the dominant path.

### 3.2. C<sub>2</sub>H<sub>2</sub> and C<sub>2</sub>H<sub>4</sub> adsorption on the Pd@Cu catalysts

Industrially, C<sub>2</sub>H<sub>2</sub> content is 0.1–1% and C<sub>2</sub>H<sub>4</sub> content is high as 89% in the raw C<sub>2</sub>H<sub>4</sub> (Yang et al., 2013; Huang et al., 2007; Vincent and Gonzalez, 2004), thus, to ensure the trace C<sub>2</sub>H<sub>2</sub> hydrogenation to produce C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>2</sub> adsorption ability must surpasses C<sub>2</sub>H<sub>4</sub> adsorption ability (Zhao et al., 2018; McCue et al., 2016). The most stable adsorption structures of H and C<sub>2</sub>H<sub>x</sub> species on different kinds of Pd@Cu is depicted in Fig. 3, and the adsorption free energy is listed in Table S1.

C<sub>2</sub>H<sub>2</sub> is stabilized at the hcp site on the Pd<sub>3</sub>@Cu, Pd<sub>7</sub>@Cu and Pd<sub>ML</sub>@Cu catalysts with the adsorption free energies of −98.1, −86.8 and −155.0 kJ·mol<sup>−1</sup>; on the Pd<sub>1</sub>@Cu, Pd<sub>2</sub>@Cu and Pd<sub>8</sub>@Cu catalysts, C<sub>2</sub>H<sub>2</sub> is stabilized at the sites consisted of the hcp and fcc sites via the C<sub>hcp</sub>-C<sub>fcc</sub> configuration with the adsorption free

Fig. 1. The surface structure of Pd@M (M = Cu, Ag, Au) alloy catalysts, (a) Pd<sub>1</sub>@M, (b) Pd<sub>2</sub>@M, (c) Pd<sub>3</sub>@M, (d) Pd<sub>7</sub>@M, (e) Pd<sub>8</sub>@M and (f) Pd<sub>ML</sub>@M.

## (1) Hydrogenation process

## (2) Polymerization process

Fig. 2. Possible reactions in the hydrogenation and polymerization processes of  $\text{C}_2\text{H}_2$  semi-hydrogenation. The (ad) and (g) stand for the adsorbed and gaseous states, respectively.

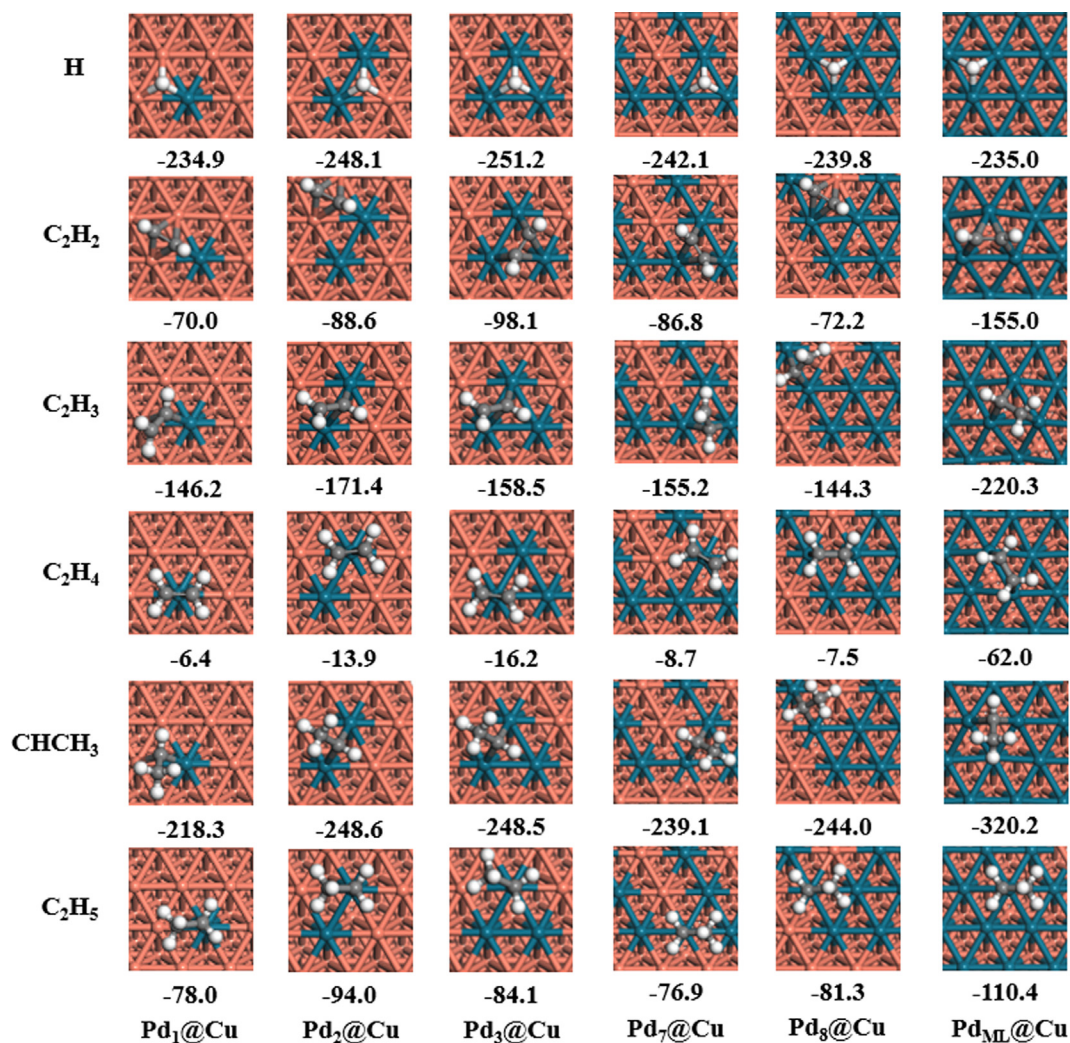

Fig. 3. The most stable adsorption configurations and the corresponding adsorption free energy ( $\text{kJ}\cdot\text{mol}^{-1}$ ) of H and  $\text{C}_2\text{H}_x$  ( $x = 2-5$ ) adsorbed on the Pd@Cu catalysts at 425 K.

energies of  $-70.0$ ,  $-88.6$  and  $-72.2$   $\text{kJ}\cdot\text{mol}^{-1}$ , respectively.  $\text{C}_2\text{H}_4$  prefers to adsorb at the bridge site on the  $\text{Pd}_8@\text{Cu}$  and  $\text{Pd}_{\text{ML}}@\text{Cu}$ , and that is at the top site on the  $\text{Pd}_1@\text{Cu}$ ,  $\text{Pd}_2@\text{Cu}$ ,  $\text{Pd}_3@\text{Cu}$  and  $\text{Pd}_7@\text{Cu}$ ; the adsorption free energies are  $-7.5$ ,  $-62.0$ ,  $-6.4$ ,  $-13.9$ ,  $-16.2$  and  $-8.7$   $\text{kJ}\cdot\text{mol}^{-1}$ , respectively; Namely, expect for  $\text{Pd}_{\text{ML}}@\text{Cu}$ , once the shell Pd ensemble is formed,  $\text{C}_2\text{H}_4$  adsorption becomes weaker on the  $\text{Pd}_1@\text{Cu}$ ,  $\text{Pd}_2@\text{Cu}$ ,  $\text{Pd}_3@\text{Cu}$ ,  $\text{Pd}_7@\text{Cu}$  and  $\text{Pd}_8@\text{Cu}$ , which is favorable for  $\text{C}_2\text{H}_4$  desorption. Thus,  $\text{C}_2\text{H}_2$  has stronger adsorption ability than  $\text{C}_2\text{H}_4$  on the six kinds of Pd@Cu catalysts, the trace  $\text{C}_2\text{H}_2$  in the raw  $\text{C}_2\text{H}_4$  material can be sufficiently adsorbed on the catalysts for  $\text{C}_2\text{H}_2$  semi-hydrogenation.

For the other adsorbed species, the adsorption free energy is in sequence of  $\text{CHCH}_3 > \text{C}_2\text{H}_3 > \text{C}_2\text{H}_5$  on Pd@Cu catalysts, the adsorption energies of these species are insensitive to the shell Pd ensemble. H adsorption free energy is in the range of  $-234.9$  to  $-251.2$   $\text{kJ}\cdot\text{mol}^{-1}$ , which also less depend on the shell Pd ensemble.

### 3.3. $\text{C}_2\text{H}_2$ semi-hydrogenation on the Pd@Cu catalysts

In  $\text{C}_2\text{H}_2$  semi-hydrogenation, for the activation free energy of the adsorbed reactants, previous works by Hu *et al.* (Yang *et al.*, 2013; Cao *et al.*, 2011; Yang *et al.*, 2014) proposed that the transition-state of adsorption process has lower energy than the total energy of the gas phase species. Thus, the maximum adsorption barrier of the species R corresponds to the value of  $TS_{\text{R}}$  ( $\text{R} = \text{C}_2\text{H}_2$  or  $\text{H}_2$ ), where  $S_{\text{R}}$  is the corresponding entropy of the species R at the reaction temperature  $T$ . Moreover, the value of  $TS_{\text{C}_2\text{H}_2}$  is higher than that of  $TS_{\text{H}_2}$ , namely,  $\text{C}_2\text{H}_2$  adsorption has the higher barrier. Further, the value of  $TS_{\text{C}_2\text{H}_2}$  is selected to represent the adsorption activation free energy of the reactants (Gad R).

In this study, the values of  $TS_{\text{C}_2\text{H}_2}$  and  $TS_{\text{H}_2}$  were calculated to be  $92.0$  and  $59.9$   $\text{kJ}\cdot\text{mol}^{-1}$  at  $425$  K, respectively. Namely,  $\text{C}_2\text{H}_2$  adsorption still has the higher adsorption barrier, which agree with the previous studies by Hu *et al.* (Yang *et al.*, 2013; Cao *et al.*, 2011; Yang *et al.*, 2014). Thus, the adsorption barrier of the reactants on Pd@Cu catalysts is represented by the adsorption barrier of  $\text{C}_2\text{H}_2$  ( $92.0$   $\text{kJ}\cdot\text{mol}^{-1}$ ). On the other hand, the overall reaction free energy of  $\text{C}_2\text{H}_2$  hydrogenation to  $\text{C}_2\text{H}_4$  is  $-206.3$   $\text{kJ}\cdot\text{mol}^{-1}$  at  $425$  K obtained from DFT calculations. Therefore, the activation free energy of the adsorbed reactants and the entropy effect are considered for the adsorption and desorption processes.

Nowadays, the previous studies by Hu *et al.* (Yang *et al.*, 2013; Yang *et al.*, 2012; Yang *et al.*, 2014; Yang *et al.*, 2016; Yang *et al.*, 2017), Mavrikakis *et al.* (Xu *et al.*, 2018), Celik *et al.* (Hook and Celik, 2017), Hafner *et al.* (Krajčí and Hafner, 2014), Kang *et al.* (Zhao *et al.*, 2018), Wang *et al.* (Ma and Wang, 2020) and Gong *et al.* (Zhao *et al.*, 2019) have proposed the simplest descriptor when  $\text{CHCH}_3$  hydrogenation path is not the dominant path, that is the energy difference between  $\text{C}_2\text{H}_4$  desorption and its hydrogenation to quantitatively and qualitatively evaluate  $\text{C}_2\text{H}_4$  selectivity. Meanwhile,  $\text{C}_2\text{H}_4$  desorption free energy is approximately equal to its adsorption free energy (Cao *et al.*, 2011). Thus,  $\text{C}_2\text{H}_4$  selectivity ( $S_{\text{sel}}$ ) is defined as follows:

$$S_{\text{sel}} = G_{a,\text{hydr}} - G_{a,\text{des}} = G_{a,\text{hydr}} - |G_{\text{ads}}| \quad (1)$$

where  $G_{a,\text{hydr}}$  corresponds to the activation free energy of the reaction  $\text{C}_2\text{H}_4 + \text{H} \rightarrow \text{C}_2\text{H}_5$ ,  $G_{a,\text{des}}$  is the adsorption free energy of  $\text{C}_2\text{H}_4$  desorption; the better  $\text{C}_2\text{H}_4$  selectivity corresponds to the more positive value of  $S_{\text{sel}}$ .

#### 3.3.1. On $\text{Pd}_1@\text{Cu}$ catalyst

As depicted in Fig. 4 and Table 1, starting with the gas phase reactants, the adsorption and desorption processes consider the activation of the adsorbed reactants and the entropy effect in the  $\text{C}_2\text{H}_2$  semi-hydrogenation.  $\text{C}_2\text{H}_4$  desorption is more favorable than  $\text{C}_2\text{H}_4$  hydrogenation in kinetics ( $6.4$  vs.  $86.1$   $\text{kJ}\cdot\text{mol}^{-1}$ ,  $S_{\text{sel}} = 79.7$  kJ

$\cdot\text{mol}^{-1}$ ),  $\text{C}_2\text{H}_4$  desorption path becomes dominant compared to  $\text{C}_2\text{H}_4$  hydrogenation path. Then, the reaction  $\text{C}_2\text{H}_3(\text{ad}) + \text{H}(\text{ad}) \rightarrow \text{C}(\text{HCH}_3(\text{ad}))$  is kinetically difficult to occur compared to the reaction  $\text{C}_2\text{H}_3(\text{ad}) + \text{H}(\text{ad}) \rightarrow \text{C}_2\text{H}_4(\text{ad})$  ( $124.8$  vs.  $54.6$   $\text{kJ}\cdot\text{mol}^{-1}$ ), that is,  $\text{C}_2\text{H}_4$  desorption path is kinetically favored compared to  $\text{CHCH}_3$  hydrogenation path. Further, the activation free energy of  $\text{C}_2\text{H}_2(\text{ad}) + \text{H}(\text{ad}) \rightarrow \text{C}_2\text{H}_3(\text{ad})$  is  $138.5$   $\text{kJ}\cdot\text{mol}^{-1}$  with the reaction free energy of  $-39.8$   $\text{kJ}\cdot\text{mol}^{-1}$ . The activation free energy of  $\text{C}_2\text{H}_2(\text{g}) + \text{H}_2(\text{g}) \rightarrow \text{C}_2\text{H}_2(\text{ad}) + 2\text{H}(\text{ad})$  is  $92.0$   $\text{kJ}\cdot\text{mol}^{-1}$  with the reaction free energy of  $-84.1$   $\text{kJ}\cdot\text{mol}^{-1}$ . Thus,  $\text{C}_2\text{H}_2$  hydrogenation on  $\text{Pd}_1@\text{Cu}$  dominantly contributes to gas phase  $\text{C}_2\text{H}_4$  formation via the desorption route.

#### 3.3.2. On the $\text{Pd}_2@\text{Cu}$ , $\text{Pd}_3@\text{Cu}$ , $\text{Pd}_7@\text{Cu}$ and $\text{Pd}_8@\text{Cu}$ catalysts

As depicted in Figs. S3–S6, similar to  $\text{Pd}_1@\text{Cu}$  catalyst,  $\text{C}_2\text{H}_4$  desorption path to produce gas phase  $\text{C}_2\text{H}_4$  is the most favorable kinetically than other two paths on the  $\text{Pd}_2@\text{Cu}$ ,  $\text{Pd}_3@\text{Cu}$ ,  $\text{Pd}_7@\text{Cu}$  and  $\text{Pd}_8@\text{Cu}$  catalysts, correspondingly,  $\text{C}_2\text{H}_4$  selectivity is  $81.2$ ,  $87.9$ ,  $151.0$  and  $75.4$   $\text{kJ}\cdot\text{mol}^{-1}$ , respectively. Thus, the  $\text{Pd}_2@\text{Cu}$ ,  $\text{Pd}_3@\text{Cu}$ ,  $\text{Pd}_7@\text{Cu}$  and  $\text{Pd}_8@\text{Cu}$  catalysts are in favor of  $\text{C}_2\text{H}_2$  hydrogenation to produce gas phase  $\text{C}_2\text{H}_4$  instead of ethane via other two paths.

#### 3.3.3. On $\text{Pd}_{\text{ML}}@\text{Cu}$ catalyst

As depicted in Fig. 5,  $\text{C}_2\text{H}_4$  desorption is more kinetically favorable than the reaction  $\text{C}_2\text{H}_4 + \text{H} \rightarrow \text{C}_2\text{H}_5$  ( $62.0$  vs.  $87.5$   $\text{kJ}\cdot\text{mol}^{-1}$ ), however,  $\text{C}_2\text{H}_3 + \text{H} \rightarrow \text{CHCH}_3$  is more kinetically superior to  $\text{C}_2\text{H}_3 + \text{H} \rightarrow \text{C}_2\text{H}_4$  ( $110.7$  vs.  $126.9$   $\text{kJ}\cdot\text{mol}^{-1}$ ); moreover, with respect to the common  $\text{C}_2\text{H}_3 + \text{H}$  species,  $\text{CHCH}_3$  hydrogenation path is more favored in kinetics compared to  $\text{C}_2\text{H}_4$  desorption path ( $-66.9$  vs.  $-50.7$   $\text{kJ}\cdot\text{mol}^{-1}$ ). Thus,  $\text{CHCH}_3$  hydrogenation path becomes dominant, which affects  $\text{C}_2\text{H}_4$  selectivity on  $\text{Pd}_{\text{ML}}@\text{Cu}$  catalyst,  $\text{C}_2\text{H}_4$  selectivity is  $-16.2$   $\text{kJ}\cdot\text{mol}^{-1}$ , which is calculated by the descriptor that is the difference of the overall energy between  $\text{CHCH}_3$  hydrogenation path and  $\text{C}_2\text{H}_4$  desorption path beginning with the common  $\text{C}_2\text{H}_3 + \text{H}$  species.

### 3.4. Activity of $\text{C}_2\text{H}_4$ formation on the Pd@Cu catalysts

Hu *et al.* (Yang *et al.*, 2013; Cao *et al.*, 2011; Yang *et al.*, 2014; Cheng and Hu, 2011; Cheng *et al.*, 2008) have proposed the two-step model to describe the activity of  $\text{C}_2\text{H}_4$  formation, which is calculated by the Eq. (2) (see details in the Supplementary Material).

$$r = \frac{k_B T}{h} = \frac{\left(1 - \frac{P_P}{P_R} e^{\frac{\Delta G}{RT}}\right)}{\frac{P_P^0}{P_R} e^{\frac{c_{\text{ad}}^{\text{ad}} - c_{\text{R}}^{\text{de}} + c_{\text{P}}^{\text{de}}}{RT}} + e^{\frac{c_{\text{P}}^{\text{de}}}{RT}}} \quad (2)$$

As listed in Table 2,  $\text{Pd}_{\text{ML}}@\text{Cu}$  exhibits the lowest activity of  $\text{C}_2\text{H}_4$  formation ( $3.06 \times 10^{-6}$   $\text{s}^{-1}\cdot\text{site}^{-1}$ ), while for the  $\text{Pd}_1@\text{Cu}$ ,  $\text{Pd}_2@\text{Cu}$ ,  $\text{Pd}_3@\text{Cu}$  and  $\text{Pd}_7@\text{Cu}$  catalysts, with the increasing of alloyed shell Pd atoms, both Pd dimer and Pd trimer are formed on the catalyst surface, the activity of  $\text{C}_2\text{H}_4$  formation gradually increased ( $8.40 \times 10^{-5}$ ,  $2.17 \times 10^3$ ,  $6.29 \times 10^4$  and  $5.66 \times 10^6$   $\text{s}^{-1}\cdot\text{site}^{-1}$ ). However, when the shell Pd atoms increase to form  $\text{Pd}_8@\text{Cu}$ , the activity of  $\text{C}_2\text{H}_4$  formation decreased to  $9.27 \times 10^2$   $\text{s}^{-1}\cdot\text{site}^{-1}$ . Among these six catalysts,  $\text{Pd}_7@\text{Cu}$  with the shell Pd ensemble of both Pd dimer and trimer exhibits the highest activity of  $\text{C}_2\text{H}_4$  formation ( $5.66 \times 10^6$   $\text{s}^{-1}\cdot\text{site}^{-1}$ ).

### 3.5. General discussion

#### 3.5.1. The influence of the shell Pd ensemble form on $\text{C}_2\text{H}_4$ formation

Based on above analysis,  $\text{C}_2\text{H}_4$  selectivity is in sequence of  $\text{Pd}_7@\text{Cu} > \text{Pd}_3@\text{Cu} > \text{Pd}_2@\text{Cu} > \text{Pd}_1@\text{Cu} > \text{Pd}_8@\text{Cu} > \text{Pd}_{\text{ML}}@\text{Cu}$  ( $151.0$ ,  $87.9$ ,  $81.2$ ,  $79.7$ ,  $75.4$  and  $-16.2$   $\text{kJ}\cdot\text{mol}^{-1}$ ). Correspondingly,  $\text{C}_2\text{H}_4$  formation rates follows the order of  $\text{Pd}_7@\text{Cu} > \text{Pd}_3@\text{Cu} > \text{Pd}_2@-$

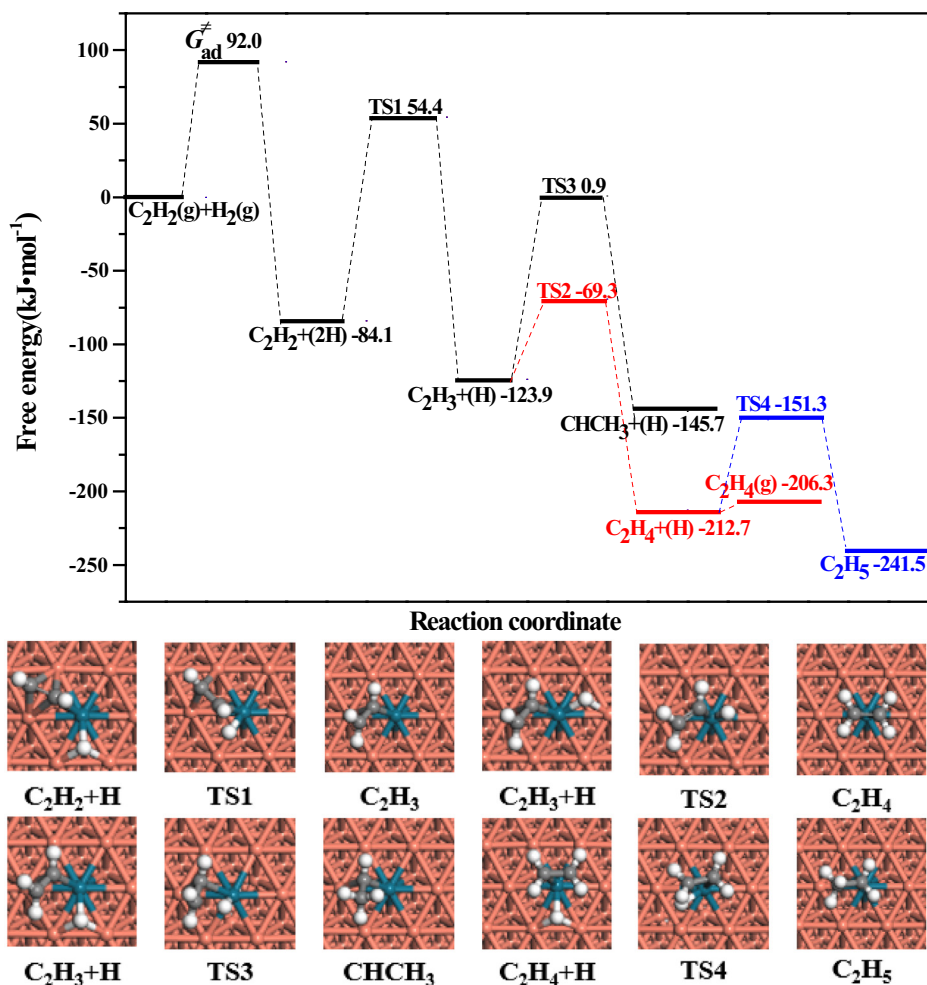

Fig. 4. Free energy profiles of  $C_2H_2$  semi-hydrogenation with the initial states, transition states and final states on  $Pd_1@Cu$  catalyst.

Table 1

The activation free energy (reaction free energy) ( $kJ \cdot mol^{-1}$ ) of  $C_2H_2$  semi-hydrogenation on the  $Pd@M$  ( $M = Cu, Ag, Au$ ) alloy catalysts.

Catalysts	Elementary reactions				
	$C_2H_2 + H \rightarrow C_2H_3$	$C_2H_3 + H \rightarrow C_2H_4$	$C_2H_3 + H \rightarrow CHCH_3$	$C_2H_4 + H \rightarrow C_2H_5$	$CHCH_3 + H \rightarrow C_2H_5$
$Pd_1@Cu$	138.5(-39.8)	54.6(-88.8)	124.8(-21.8)	86.1(-28.8)	—
$Pd_2@Cu$	78.2(-44.2)	73.3(-67.2)	225.6(-15.2)	95.1(-16.2)	—
$Pd_3@Cu$	66.3(-14.5)	49.7(-74.2)	221.7(-19.8)	104.1(-1.7)	—
$Pd_7@Cu$	50.4(-59.9)	68.5(-77.2)	229.5(-20.8)	159.7(5.0)	—
$Pd_8@Cu$	81.2(-36.6)	83.0(-80.0)	196.1(-29.7)	82.9(-8.9)	—
$Pd_{ML}@Cu$	84.4(23.3)	126.9(-90.7)	110.7(-57.6)	87.5(-3.4)	160.3(-15.9)
$Pd_7@Ag$	50.7(-28.6)	83.3(-51.6)	119.4(3.6)	90.0(5.5)	—
$Pd_{ML}@Ag$	103.7(31.0)	100.2(-22.3)	254.1(4.7)	169.8(40.5)	103.9(7.0)
$Pd_7@Au$	61.9(-8.7)	85.2(-43.3)	197.6(-12.4)	75.2(-10.5)	—
$Pd_{ML}@Au$	83.6(30.5)	118.5(-17.0)	258.0(14.0)	110.6(35.8)	135.7(8.8)

$Cu > Pd_8@Cu > Pd_1@Cu > Pd_{ML}@Cu$  ( $5.66 \times 10^6$ ,  $6.29 \times 10^4$ ,  $2.17 \times 10^3$ ,  $9.27 \times 10^2$ ,  $8.40 \times 10^{-5}$  and  $3.06 \times 10^{-6} s^{-1} \cdot site^{-1}$ ).

As depicted in Fig. 1, the shell surface structure of  $Pd@Cu$  catalysts showed that  $Pd_1@Cu$ ,  $Pd_2@Cu$  and  $Pd_3@Cu$  have the surface isolated Pd atom, Pd dimer, and Pd trimer, respectively;  $Pd_7@Cu$  has both the surface Pd dimer and trimer. While  $Pd_{ML}@Cu$  without the surface Pd dimer and trimer present the surface characteristic of the pure Pd.  $Pd_8@Cu$  catalyst with more than four Pd atoms polymers has poor  $C_2H_4$  formation activity. Among them,  $Pd_2@Cu$  with the shell Pd dimer and  $Pd_3@Cu$  with the shell Pd trimer exhibit excellent  $C_2H_4$  selectivity and its formation activity, especially,  $Pd_7@Cu$  with the shell Pd dimer and trimer shows the best  $C_2H_4$  selectivity and its formation activity.

Further, as depicted in Fig. 3, the most stable adsorption site of both H and  $C_2H_x$  ( $x = 2-5$ ) on  $Pd@Cu$  catalysts is at the Pd-Cu interface site near the Pd dimer and trimer. Moreover, the initial state (IS), transition state (TS) and final state (FS) are almost adsorbed at the Pd dimer on  $Pd_2@Cu$ . Similarly, the IS, TS and FS prefer to be located at the Pd trimer on  $Pd_3@Cu$ . Especially, for the  $Pd_7@Cu$  and  $Pd_8@Cu$ , the IS, TS and FS are located at the Pd-Cu interface site near the Pd dimer and trimer.

Based on the above analysis, the existence forms of shell Pd ensemble obviously affect  $C_2H_4$  selectivity and its formation activity on  $Pd@Cu$  catalysts; meanwhile, there must be a synergy between Pd and Cu atoms near the shell Pd dimer and trimer to increase  $C_2H_4$  selectivity and its formation activity.

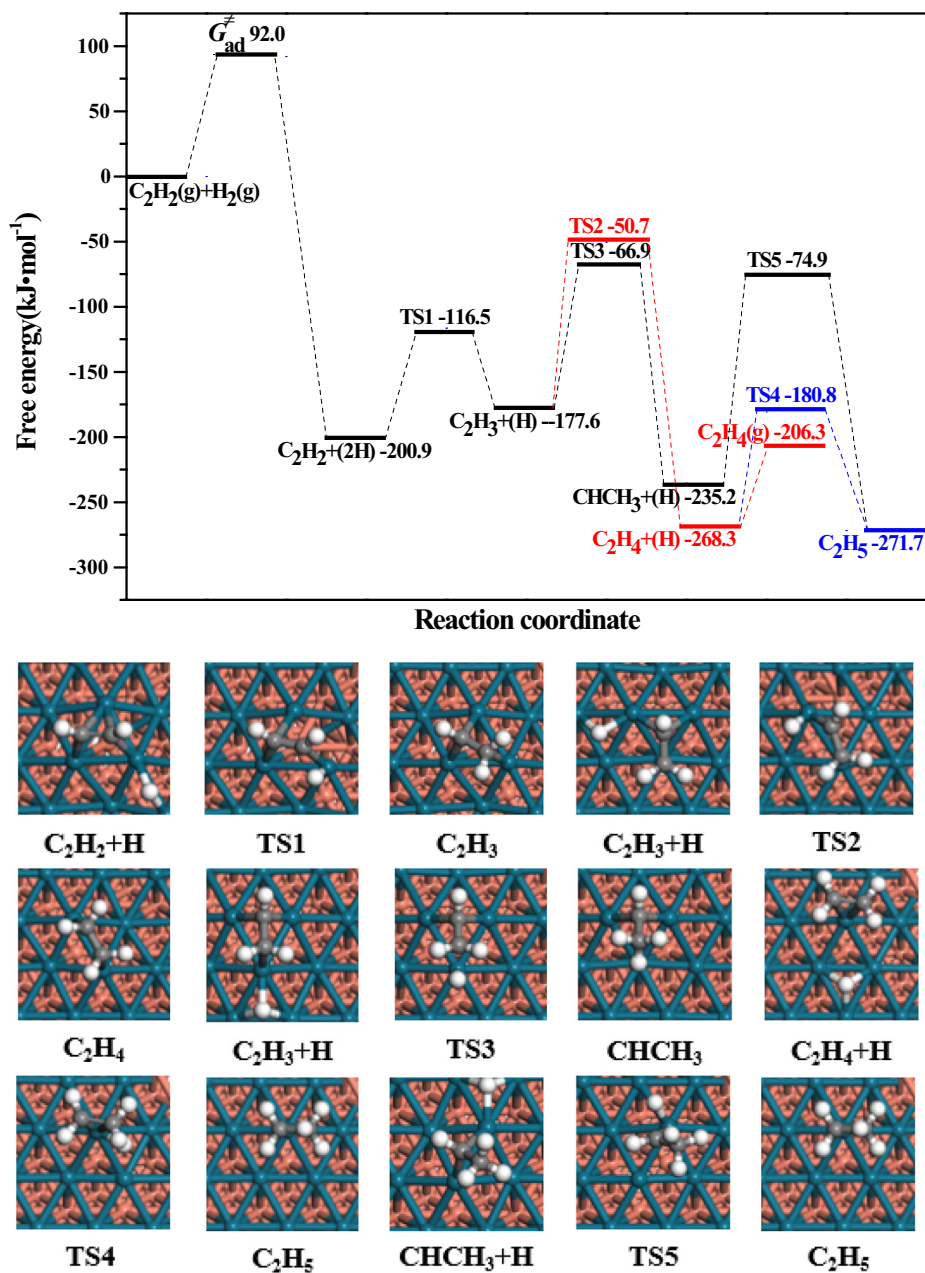

Fig. 5. Free energy profiles of  $C_2H_2$  semi-hydrogenation with the initial states, transition states and final states on  $Pd_{ML}@Cu$  catalyst.

Table 2

The values of  $C_2H_4$  selectivity ( $S_{sel}/kJ \cdot mol^{-1}$ ), formation rate ( $r/s^{-1} \cdot site^{-1}$ ) and the average Bader charge ( $e$ ) obtained by the surface Pd atoms on the  $Pd@M$  ( $M = Cu, Ag, Au$ ) alloy catalysts.

Catalysts	$S_{sel}$	$r$	$e$
$Pd_1@Cu$	79.7	$8.40 \times 10^{-5}$	0.941
$Pd_2@Cu$	81.2	$2.17 \times 10^3$	0.944
$Pd_3@Cu$	87.9	$6.29 \times 10^4$	0.949
$Pd_7@Cu$	151.0	$5.66 \times 10^6$	0.847
$Pd_8@Cu$	75.4	$9.27 \times 10^2$	0.870
$Pd_{ML}@Cu$	-16.2	$3.06 \times 10^{-6}$	0.748
$Pd_7@Ag$	71.8	$1.68 \times 10^6$	0.958
$Pd_{ML}@Ag$	143.6	$1.02 \times 10^{-9}$	0.749
$Pd_7@Au$	47.8	$3.50 \times 10^3$	0.999
$Pd_{ML}@Au$	74.5	$4.30 \times 10^{-6}$	0.749

### 3.5.2. Electronic properties analysis of $Pd@Cu$ catalysts

To better clarify the influences of  $Pd@Cu$  with different forms of shell Pd ensemble on  $C_2H_4$  selectivity and its formation activity, a projected density of states ( $pDOS$ ) and  $d$ -band center of  $Pd@Cu$  catalysts was conducted to explain the microscopic essence, see Fig. S12, the  $d$ -band center of  $Pd@Cu$  with different forms of shell Pd ensemble is in the sequence of  $Pd_{ML}@Cu$  ( $-2.501$ ) <  $Pd_1@Cu$  ( $-2.500$ ) <  $Pd_8@Cu$  ( $-2.493$ ) <  $Pd_7@Cu$  ( $-2.487$ ) <  $Pd_3@Cu$  ( $-2.443$ ) <  $Pd_2@Cu$  ( $-2.429$ ).

As depicted in Fig. 6a and b, the  $d$ -band center of the shell Pd atoms and their coordinated Cu atoms has a volcano curve relationship with  $C_2H_4$  selectivity and its formation activity on  $Pd@Cu$  catalysts, namely, the  $d$ -band center of both  $Pd_{ML}@Cu$  and  $Pd_1@Cu$  shifts away compared to the Fermi level, which exhibits the lower  $C_2H_4$  selectivity and formation activity; whereas the  $d$ -band center of both  $Pd_2@Cu$  and  $Pd_3@Cu$  with the shell Pd ensemble of dimer

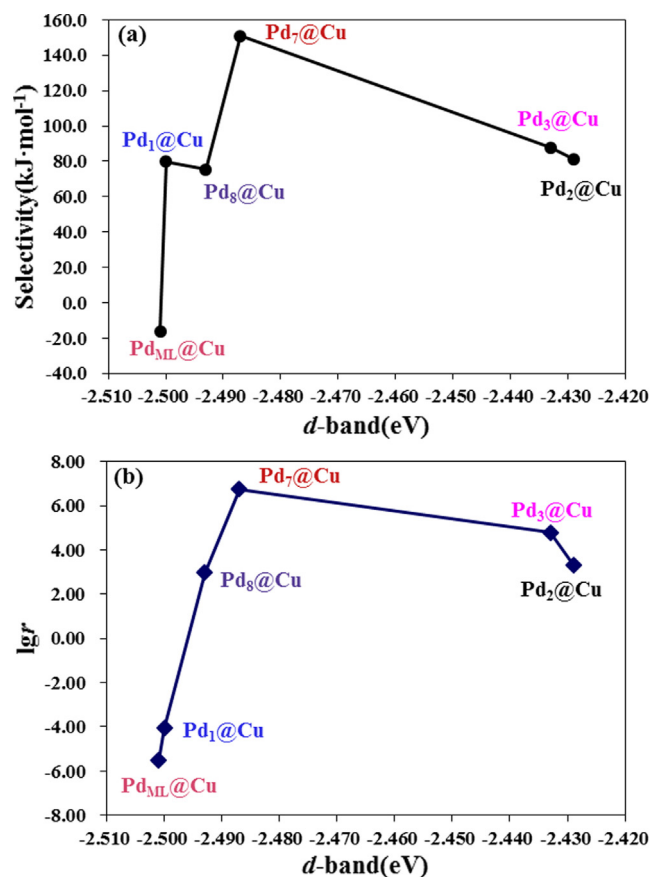

Fig. 6. The relationship between the selectivity of C<sub>2</sub>H<sub>4</sub> (kJ·mol<sup>-1</sup>) and *d*-band center (a), that between the formation rate of C<sub>2</sub>H<sub>4</sub> (log r/s<sup>-1</sup>·site<sup>-1</sup>) and *d*-band center (b) on the Pd@Cu catalysts.

and trimer shifts toward the Fermi level, exhibiting better catalytic performance. Interestingly, Pd<sub>7</sub>@Cu catalyst with the moderate *d*-band center presents the best C<sub>2</sub>H<sub>4</sub> selectivity and its formation activity, which may be attributed to the special surface geometry structure that is the shell Pd ensemble with both Pd dimer and Pd trimer. Thus, the existence form of shell Pd ensemble alters the *d*-orbital distribution of Pd@Cu catalysts, and the synergetic interaction of electronic properties and geometry structure affects the catalytic performance of Pd@Cu catalysts in C<sub>2</sub>H<sub>2</sub> semi-hydrogenation; Namely, the catalytic performance not only depends on the *d*-band center of the active center but also depends on the shell Pd ensemble forms. In addition, previous studies (Liu et al., 2013; Deng et al., 2020; Ando et al., 2018; Fu et al., 2020; Song et al., 2019) also demonstrated that the catalytic activity has a volcano curve relationship with the *d*-band center of the catalysts, and the catalyst with a moderate *d*-band center exhibits the best catalytic performance, which is attributed to that the adsorption ability of the adsorbed species have a close correlation with the *d*-band center, suggesting that the farther the *d*-band center of the catalyst surface from the Fermi level is, the stronger the adsorption ability of the species on the catalysts is; when the adsorption ability is too strong, the adsorbed species is difficult to participate into the reaction, whereas the adsorption ability is too weak, the adsorbed species cannot be effectively activated, and it is difficult to initiate the subsequent reaction; thus, a moderate adsorption ability is more beneficial for the adsorbed species to initiate the subsequent reaction.

Based on the above analysis, a moderate *d*-band center shows excellent catalytic performance. As presented in Fig. 3, the relationship between the adsorption energy of adsorbed species and

the *d*-band is also roughly the same trend. The moderate adsorption ability of C<sub>2</sub>H<sub>2</sub> on Pd<sub>7</sub>@Cu catalyst is conducive to its hydrogenation and shows high C<sub>2</sub>H<sub>4</sub> formation activity; and the moderate adsorption ability of C<sub>2</sub>H<sub>4</sub> is beneficial to its desorption and present better C<sub>2</sub>H<sub>4</sub> selectivity.

On the other hand, the average Bader charge of shell Pd atoms is examined, see Table 2; the charge density difference of Pd@Cu is also considered, as depicted in Fig. 7, correspondingly, the average Bader charge of the shell Pd atoms decreases in sequence of Pd<sub>3</sub>@Cu (0.949 *e*) > Pd<sub>2</sub>@Cu (0.944 *e*) > Pd<sub>1</sub>@Cu (0.941 *e*) > Pd<sub>8</sub>@Cu (0.870 *e*) > Pd<sub>7</sub>@Cu (0.847 *e*) > Pd<sub>ML</sub>@Cu (0.748 *e*). Meanwhile, the charge density differences in Fig. 7a–f shows that the electron accumulation decreases at the region of Pd atoms with the decreasing of the average Bader charge of the shell Pd atoms. Thus, both Pd<sub>1</sub>@Cu and Pd<sub>ML</sub>@Cu catalysts at the region of Pd atoms corresponding to most and least electron accumulation have the lowest catalytic performance. Although the region of Pd atoms of Pd<sub>3</sub>@Cu and Pd<sub>2</sub>@Cu corresponds to the most electron accumulation, both catalysts present better catalytic performance, which is probably attributed to the shell Pd ensemble form. Pd<sub>7</sub>@Cu catalyst at the region of Pd atoms with moderate electron accumulation exhibits the excellent catalytic performance toward C<sub>2</sub>H<sub>2</sub> semi-hydrogenation.

Generally, Pd<sub>7</sub>@Cu with the shell Pd ensemble of dimer and trimer presents the best C<sub>2</sub>H<sub>4</sub> selectivity and its formation activity. Thus, it is proposed that this type of catalysts with the shell Pd ensemble of dimer and trimer can be also applied to other kinds of Pd@M catalysts in C<sub>2</sub>H<sub>2</sub> semi-hydrogenation.

### 3.5.3. The influence of shell Pd ensemble in Pd@M (M = Ag, Au) on C<sub>2</sub>H<sub>4</sub> formation

Similar to Pd@Cu catalysts, aiming at confirming whether other metal core with the shell Pd ensemble of dimer and trimer still favor C<sub>2</sub>H<sub>4</sub> formation with high selectivity and activity, C<sub>2</sub>H<sub>2</sub> semi-hydrogenation on the Pd<sub>7</sub>@M and Pd<sub>ML</sub>@M (M = Ag, Au) catalysts were considered (see details in the Supplementary Material).

C<sub>2</sub>H<sub>2</sub> adsorption is still much stronger than C<sub>2</sub>H<sub>4</sub> adsorption on the Pd<sub>7</sub>@Ag, Pd<sub>ML</sub>@Ag, Pd<sub>7</sub>@Au and Pd<sub>ML</sub>@Au (see Table S1 and Fig. S7). As depicted in Figs. S8–S11, the formation of gas phase C<sub>2</sub>H<sub>4</sub> via C<sub>2</sub>H<sub>4</sub> desorption path is kinetically favored compared to other two hydrogenation paths to form ethane on the Pd<sub>7</sub>@Ag, Pd<sub>ML</sub>@Ag, Pd<sub>7</sub>@Au and Pd<sub>ML</sub>@Au, correspondingly, C<sub>2</sub>H<sub>4</sub> selectivity is 71.8, 143.6, 47.8 and 74.5 kJ·mol<sup>-1</sup>, the formation rates are 1.68 × 10<sup>6</sup>, 1.02 × 10<sup>-9</sup>, 3.50 × 10<sup>3</sup> and 4.30 × 10<sup>-6</sup> s<sup>-1</sup>·site<sup>-1</sup>, respectively. Previously reported works by Wang et al. (Wang et al., 2020) found that C<sub>2</sub>H<sub>4</sub> hydrogenation to C<sub>2</sub>H<sub>5</sub> is energetically comparable to its desorption over Pd<sub>2</sub>@Ag with Pd dimer (44.3 vs. 47.1 kJ·mol<sup>-1</sup>), showing a poor C<sub>2</sub>H<sub>4</sub> selectivity, meanwhile, Pd<sub>3</sub>@Ag with Pd trimer exhibits better catalytic performance toward C<sub>2</sub>H<sub>4</sub> formation (*S*<sub>sel</sub> = 44.7 kJ·mol<sup>-1</sup>, *r* = 7.11 × 10<sup>3</sup> s<sup>-1</sup>·site<sup>-1</sup>); thus, Pd<sub>7</sub>@Ag shows the best catalytic activity and selectivity toward C<sub>2</sub>H<sub>4</sub> formation among Pd@Ag catalysts.

Markedly, both Pd<sub>7</sub>@Ag and Pd<sub>7</sub>@Au with the shell Pd ensemble of dimer and trimer exhibit better C<sub>2</sub>H<sub>4</sub> formation activity compared to Pd<sub>ML</sub>@Ag and Pd<sub>ML</sub>@Au catalysts with a whole layer of surface Pd. Moreover, the average charge of the shell Pd atoms for Pd<sub>7</sub>@Ag catalyst is more than that of Pd<sub>ML</sub>@Ag (0.958 *e* vs. 0.749 *e*), similarly, the average charge of the shell Pd atoms for Pd<sub>7</sub>@Au is more than that of Pd<sub>ML</sub>@Au (0.999 *e* vs. 0.749 *e*), which is also confirmed by the charge density difference, see Fig. 7g–j.

### 3.5.4. The influence of the core metal type for Pd<sub>7</sub>@M catalysts on C<sub>2</sub>H<sub>4</sub> formation

As mentioned above, among Pd<sub>7</sub>@M (M = Cu, Ag, Au) catalysts, Pd<sub>7</sub>@Cu presents the highest C<sub>2</sub>H<sub>4</sub> formation activity (5.66 × 10<sup>6</sup> vs. 1.68 × 10<sup>6</sup>, 3.50 × 10<sup>3</sup> s<sup>-1</sup>·site<sup>-1</sup>) and the best C<sub>2</sub>H<sub>4</sub> selectivity

**Fig. 7.** Electron density difference contour maps of Pd@M (M = Cu, Ag, Au) alloy catalysts (a) Pd<sub>1</sub>@Cu, (b) Pd<sub>2</sub>@Cu, (c) Pd<sub>3</sub>@Cu, (d) Pd<sub>7</sub>@Cu, (e) Pd<sub>8</sub>@Cu, (f) Pd<sub>ML</sub>@Cu, (g) Pd<sub>7</sub>@Ag, (h) Pd<sub>ML</sub>@Ag, (i) Pd<sub>7</sub>@Au, (j) Pd<sub>ML</sub>@Au. Blue represents the electron depletion regions, and red represents the electron accumulation regions. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

(151.0 vs. 71.8, 47.8 kJ·mol<sup>-1</sup>). Namely, for the same shell Pd ensemble consisted of dimer and trimer, the kinds of metal core obviously affect C<sub>2</sub>H<sub>4</sub> selectivity and its formation activity.

As depicted in Fig. S12, the *d*-band center of Pd<sub>7</sub>@M (M = Cu, Ag, Au) follows the order of Pd<sub>7</sub>@Au (-3.496) < Pd<sub>7</sub>@Ag (-3.374) < Pd<sub>7</sub>@Cu (-2.487), in which both Pd<sub>7</sub>@Au and Pd<sub>7</sub>@Ag shifts away compared to the Fermi level to present the lower C<sub>2</sub>H<sub>4</sub> selectivity and its formation activity, whereas the *d*-band center of Pd<sub>7</sub>@Cu stays near the Fermi level to exhibit the best catalytic performance. Moreover, as listed in Table 2, the average charge of the shell Pd atoms of Pd<sub>7</sub>@Cu (0.847 *e*) is at the medium level compared to that of Pd<sub>7</sub>@Ag and Pd<sub>7</sub>@Au (0.958 and 0.999 *e*), thus, Pd<sub>7</sub>@Cu presents the best catalytic performance toward C<sub>2</sub>H<sub>2</sub> semi-hydrogenation.

Thus, C<sub>2</sub>H<sub>4</sub> selectivity and its formation activity on the Pd<sub>7</sub>@M (M = Cu, Ag, Au) catalysts also have a close relationship with the kinds of the metal core, taking C<sub>2</sub>H<sub>4</sub> selectivity and its formation activity into account, Pd<sub>7</sub>@Cu presents the best C<sub>2</sub>H<sub>4</sub> selectivity (151.0 kJ·mol<sup>-1</sup>) and its formation activity (5.66 × 10<sup>6</sup> s<sup>-1</sup>·site<sup>-1</sup>).

### 3.5.5. The influence of shell Pd ensemble in Pd@M (M = Cu, Ag, Au) on H<sub>2</sub> dissociation

Since H<sub>2</sub> dissociation is also the key step to provide hydrogen source for C<sub>2</sub>H<sub>2</sub> semi-hydrogenation, as depicted in Fig. S13, H<sub>2</sub> dissociation was further investigated on the Pd@M (M = Cu, Ag, Au) catalysts, the results show that H<sub>2</sub> dissociation is much easier in kinetics on the Pd<sub>1</sub>@Cu, Pd<sub>2</sub>@Cu, Pd<sub>3</sub>@Cu, Pd<sub>7</sub>@Cu, Pd<sub>8</sub>@Cu, Pd<sub>ML</sub>@Cu, Pd<sub>7</sub>@Ag, Pd<sub>ML</sub>@Ag, Pd<sub>7</sub>@Au and Pd<sub>ML</sub>@Au catalysts, the corresponding activation free energies are 36.6, 21.9, 25.6, 26.0, 32.9, 32.3, 23.1, 16.5, 27.6 and 15.5 kJ·mol<sup>-1</sup>, respectively. Namely, Pd@M (M = Cu, Ag, Au) catalysts exhibit high catalytic activity toward H<sub>2</sub> dissociation into H atoms on these ten kinds of catalysts considered, which is not the rate-determining step of C<sub>2</sub>H<sub>2</sub> semi-hydrogenation, and can provide enough hydrogen sources for C<sub>2</sub>H<sub>2</sub> semi-hydrogenation.

### 3.5.6. The influence of Pd<sub>7</sub>@M (M = Cu, Ag, Au) on green oil formation

As depicted in Fig. S5, for the polymerization process on Pd<sub>7</sub>@Cu catalyst, the coupling of C<sub>2</sub>H<sub>2</sub> + C<sub>2</sub>H<sub>3</sub> to C<sub>4</sub>H<sub>5</sub> is kinetically favorable among three coupling paths. However, starting from the adsorbed C<sub>2</sub>H<sub>3</sub> species, the polymerization process via the coupling of C<sub>2</sub>H<sub>2</sub> + C<sub>2</sub>H<sub>3</sub> to C<sub>4</sub>H<sub>5</sub> is more difficult in kinetics than C<sub>2</sub>H<sub>2</sub> hydrogenation process via C<sub>2</sub>H<sub>4</sub> desorption path (93.1 vs. 68.5 kJ·mol<sup>-1</sup>). Thus, Pd<sub>7</sub>@Cu catalyst not only favors the hydrogenation process to produce gas phase C<sub>2</sub>H<sub>4</sub>, but also effectively inhibits the polymerization process to form the green oil.

As depicted in Fig. S8, for Pd<sub>7</sub>@Ag catalyst, beginning with the adsorbed C<sub>2</sub>H<sub>3</sub> species, the hydrogenation process via C<sub>2</sub>H<sub>4</sub> desorption path is energetically competitive with the polymerization process via the coupling route of C<sub>2</sub>H<sub>2</sub> + C<sub>2</sub>H<sub>3</sub> to C<sub>4</sub>H<sub>5</sub> (83.3 vs. 85.3 kJ·mol<sup>-1</sup>). Thus, different from Pd<sub>7</sub>@Cu catalyst, Pd<sub>7</sub>@Ag favors C<sub>2</sub>H<sub>2</sub> semi-hydrogenation to form gas phase C<sub>2</sub>H<sub>4</sub>, however, the polymerization to form the green oil would affect the selectivity of gas phase C<sub>2</sub>H<sub>4</sub>. Similarly, as depicted in Fig. S10, for Pd<sub>7</sub>@Au catalyst, the polymerization process via the coupling route of C<sub>2</sub>H<sub>2</sub> + C<sub>2</sub>H<sub>3</sub> to C<sub>4</sub>H<sub>5</sub> is superior to its hydrogenation process via C<sub>2</sub>H<sub>4</sub> desorption path (66.4 vs. 85.2 kJ·mol<sup>-1</sup>), namely, Pd<sub>7</sub>@Au easily produce green oil to deactivate the catalyst.

### 3.5.7. Microkinetic modeling on the Pd<sub>7</sub>@M (M = Cu, Ag, Au) catalysts

Microkinetic modeling (Zhang et al., 2018; Gonçalves et al., 2020; Ayodele et al., 2020) is considered to probe into the catalytic activity and selectivity of C<sub>2</sub>H<sub>4</sub> formation in C<sub>2</sub>H<sub>2</sub> semi-hydrogenation on the Pd<sub>7</sub>@M (M = Cu, Ag, Au) catalysts under typical experimental conditions (P<sub>C<sub>2</sub>H<sub>2</sub></sub> = 0.01 atm, P<sub>H<sub>2</sub></sub> = 0.1 atm, and T = 425 K). The results show that the reaction rate of C<sub>2</sub>H<sub>4</sub> formation is 1.15 × 10<sup>2</sup> s<sup>-1</sup>·site<sup>-1</sup> and the relative selectivity of C<sub>2</sub>H<sub>4</sub> is 100% on the Pd<sub>7</sub>@Cu catalyst; meanwhile, those are 5.05 × 10<sup>-1</sup> s<sup>-1</sup>·site<sup>-1</sup> and 100% on Pd<sub>7</sub>@Ag, as well as 1.43 × 10<sup>0</sup> s<sup>-1</sup>·site<sup>-1</sup> and 100% on Pd<sub>7</sub>@Au catalysts, suggesting that Pd<sub>7</sub>@Cu catalyst

presents the highest activity of  $C_2H_4$  formation (see details in the Supplementary Material), which agrees with the results obtained by the two-step model. Due to the impacts of surface species coverage, there is a certain degree of difference in the activity of  $C_2H_4$  formation between two-step model and microkinetic modeling, however, both methods can be used to qualitatively and quantitatively judge  $C_2H_4$  formation activity. Namely, the two-step model has a certain degree of rationality to determine  $C_2H_4$  formation activity.

Overall, the catalytic performance of the core-shell Pd@M (M = Cu, Ag and Au) catalysts toward  $C_2H_2$  semi-hydrogenation is closely related to the existence form of shell Pd ensemble, in which Pd<sub>7</sub>@M catalysts with the shell Pd ensemble consisted of dimer and trimer exhibit the best  $C_2H_4$  selectivity and its formation activity compared to Pd@M catalysts with other forms of shell Pd ensemble. On the other hand, among three kinds of Pd<sub>7</sub>@M (M = Cu, Ag and Au) catalysts with the shell Pd ensemble of dimer and trimer, although both Pd<sub>7</sub>@Au and Pd<sub>7</sub>@Ag catalysts exhibit better  $C_2H_4$  selectivity and its formation activity in the hydrogenation process, the green oil formation in the polymerization process is also easier than the gas phase  $C_2H_4$  formation, namely, both Pd<sub>7</sub>@Au and Pd<sub>7</sub>@Ag catalysts are easily deactivated due to green oil formation. However, Pd<sub>7</sub>@Cu not only favor  $C_2H_2$  hydrogenation process to form gas phase  $C_2H_4$  with the highest activity and selectivity, but also effectively inhibit the polymerization process to green oil that deactivate the catalysts, suggesting that Pd<sub>7</sub>@Cu with the shell Pd ensemble consisted of dimer and trimer is a promising catalyst applied in  $C_2H_2$  semi-hydrogenation.

Thus, it is proposed that the catalysts with the shell Pd ensemble of dimer and trimer can be also applied to other kinds of the core-shell catalysts consisted of the noble metal shell and the non-noble metal core in  $C_2H_2$  semi-hydrogenation. Our study provides the valuable structure clue for the design of highly efficient core-shell catalyst consisted of the shell with the noble metal and the core with the non-noble metal; and it is believed that controlling the ensemble form of shell noble-metal may be a good way to adjust the catalytic performance toward the selective hydrogenation of other alkynes.

#### 4. Conclusion

This study employed DFT and microkinetic modeling calculations to fully elucidate the mechanism of  $C_2H_2$  semi-hydrogenation on the core-shell Pd<sub>shell</sub>@Cu<sub>core</sub> catalysts, aiming at revealing the influences of shell Pd ensemble form on  $C_2H_4$  selectivity and its formation activity. Pd<sub>1</sub>@Cu, Pd<sub>2</sub>@Cu, Pd<sub>3</sub>@Cu, Pd<sub>7</sub>@Cu, Pd<sub>8</sub>@Cu and Pd<sub>ML</sub>@Cu were constructed to model Pd@Cu catalysts with different forms of shell Pd ensemble. Further, the obtained structure clues are applied to the Pd@Ag and Pd@Au catalysts to confirm the obtained structural information. The results showed that Pd<sub>ML</sub>@Cu exhibits the lowest catalytic performance among the Pd@Cu catalysts; Pd<sub>7</sub>@Cu catalyst with the shell Pd ensemble of dimer and trimer exhibits the best  $C_2H_4$  selectivity and its formation activity. The same interesting results are also validated on the Pd<sub>7</sub>@Ag and Pd<sub>7</sub>@Au catalysts compared with other kinds of Pd@Ag and Pd@Au catalysts with different shell Pd ensembles. The analysis of electronic properties unveiled that the better catalytic performance of Pd<sub>7</sub>@M (M = Cu, Ag, Au) with the shell Pd ensemble of dimer and trimer is ascribed to the moderate charge density and charge. Thus, adjusting the shell Pd ensemble of the core-shell alloy catalysts is an exceptional method to enhance the catalytic performance of gas phase  $C_2H_4$  formation in  $C_2H_2$  semi-hydrogenation.
