## ABSTRACT

The Cu<sub>x</sub>M<sub>y</sub> and Pd<sub>x</sub>N<sub>y</sub> intermetallic compounds (IMCs) have exhibited better catalytic performance in hydrogenation reactions; however, for C<sub>2</sub>H<sub>2</sub> selective hydrogenation, the most suitable partner metal type and ratio among Cu<sub>x</sub>M<sub>y</sub> and Pd<sub>x</sub>N<sub>y</sub> still remain unclear. This study investigated C<sub>2</sub>H<sub>2</sub> selective hydrogenation on the Cu<sub>x</sub>M<sub>y</sub> (M = Zn, Pt, Ni, Pd, Au and Ag) and Pd<sub>x</sub>N<sub>y</sub> (N = Zn, Ga, In, Sn, Cu, Ag and Au) with different Cu/M and Pd/N ratios using density functional theory calculations, the results reveal that Cu<sub>3</sub>Pd<sub>1</sub> IMCs with the surface isolated single-atom Pd anchored into the IMCs bulk as active center may serve as a promising catalyst for C<sub>2</sub>H<sub>2</sub> selective hydrogenation due to industrially practical activity and selectivity for C<sub>2</sub>H<sub>4</sub> formation, thermal stability, sufficient hydrogen source and green oil suppression, which is better than the previously reported single-atom Pd catalysts. This work would provide a guideline to design and screen out promising intermetallic compounds to catalyze selective hydrogenation of alkynes.

## 1. Introduction

In the process of C<sub>2</sub>H<sub>4</sub> production by pyrolyzing petroleum hydrocarbons, trace C<sub>2</sub>H<sub>2</sub> can be generated, which not only reduces the property of ethylene polymer, but also leads to the catalyst deactivation of C<sub>2</sub>H<sub>4</sub> polymerization due to green oil formation, so trace C<sub>2</sub>H<sub>2</sub> must be removed from the rich-feedstock C<sub>2</sub>H<sub>4</sub> [1,2]. Commonly, C<sub>2</sub>H<sub>2</sub> selective hydrogenation to C<sub>2</sub>H<sub>4</sub> is an effective method [3,4]. Nowadays, Pd-based catalysts have been industrially used to catalyze the hydrogenation of C<sub>2</sub>H<sub>2</sub> to C<sub>2</sub>H<sub>4</sub> [5,6], however, the formation of the hydrides and carbide species for Pd-based catalysts are easy to deactivate the catalyst [7,8]. In recent years, Cu-based catalysts have attracted extensive interests due to high C<sub>2</sub>H<sub>4</sub> selectivity [9,10]; however, they have low catalytic activity and favored the C–C polymerization to form green oil leading to catalyst deactivation [9,11]. Thus, developing the catalysts with high activity, high selectivity and high stability have attracted increasing interest [12–18]. Among them, the single-atom catalysts show excellent catalytic performance in C<sub>2</sub>H<sub>2</sub> selective hydrogenation due to high activity and atomic utilization [15–18], however, the decreased stability of the single-atom catalysts and the easy occurrence of agglomeration also deactivate the catalyst [19].

Within the last ten decades, the intermetallic compounds (IMCs) have attracted extensive attention in catalytic hydrogenation due to their ordered atomic arrangement, unique electronic and structural characteristics, and excellent stability [20,21]. This type of catalyst can effectively separate active centers, and present unique catalytic performance [22–28]. For example, Wang *et al.* [24] experimentally showed Cu<sub>x</sub>Zn (x = 1,3) IMCs have better activity, selectivity, and higher stability for butadiene selective hydrogenation compared to Cu, which was ascribed to carbon deposit reduction. 4-aminophenylacetylene selectivity in 4-nitrophenylacetylene selective hydrogenation on PtZn IMCs is superior to that on the single-atom Pt and Pt nanoparticles, which is attributed to the easier adsorption of nitro groups by Zn atoms [25]. The experimentally prepared Ni<sub>x</sub>M<sub>y</sub> (M = Ga, Sn) IMCs with uniform size by Liu *et al.* [26] showed better C<sub>2</sub>H<sub>4</sub> selectivity and the stability compared to Pd-based catalysts. Liu *et al.* [22] experimentally found an enhanced catalytic performance of CuNi IMCs for C<sub>2</sub>H<sub>2</sub> selective hydrogenation due to the presence of isolated metal active center and the alloying effect of Ni and Cu. Zhou *et al.* [20] experimentally showed that Pd-Zn-Pd ensembles of PdZn IMCs promote H<sub>2</sub> dissociation and C<sub>2</sub>H<sub>4</sub> desorption, which enhance C<sub>2</sub>H<sub>4</sub> selectivity. Feng *et al.* [6] experimentally and

theoretically showed that PdIn(110) surface with the Pd single-atom as active centers has the elevated  $C_2H_4$  selectivity.

As mentioned above, the intermetallic compounds have presented excellent catalytic performance toward selective hydrogenation reactions; moreover, some studies found the excellent catalytic performance of Cu or Pd intermetallic compounds toward  $C_2H_2$  selective hydrogenation. However, to date, few studies have been carried out to examine the influences of the partner metal type and its ratio in the Cu or Pd intermetallic compounds on the catalytic performance of  $C_2H_2$  hydrogenation, which still remain elusive; the surface structure characteristics of intermetallic compounds with excellent catalytic performance are also unclear. Further, the most suitable Cu or Pd intermetallic compounds remain unknown.

In order to solve above issues, this study is designed to perform a systematical study about  $C_2H_2$  selective hydrogenation on a series of Cu and Pd intermetallic compounds with different partner metal types and ratios, which include the  $Cu_xM_y$  ( $M = Zn, Pt, Ni, Pd, Au$  and  $Ag$ ) and  $Pd_xN_y$  ( $N = Zn, Ga, In, Sn, Cu, Ag$  and  $Au$ ) IMCs corresponding to different Cu/M and Pd/N ratios of 1/1, 3/1 and 1/3. The results are expected to obtain the most suitable partner metal type and ratio among  $Cu_xM_y$  and  $Pd_xN_y$  IMCs catalysts with superior performance in  $C_2H_2$  selective hydrogenation, and provide a guideline to design and screen out promising intermetallic compound catalysts for selective hydrogenation of alkynes.

## 2. Computational details

### 2.1. Computational method

The present DFT calculations were implemented by the Dmol<sup>3</sup> code [29,30] in Materials Studio 8.0 for  $Cu_xM_y$  ( $M = Zn, Pt, Pd, Au$  and  $Ag$ ) and  $Pd_xN_y$  ( $N = Zn, Ga, In, Sn, Cu, Ag$  and  $Au$ ) IMCs catalysts. The GGA and PBE [31,32] were applied to treat the exchange-correlation potential. The effective core potential (ECP) basis set was performed for IMCs, and the all-electron basis was applied to other species. The valence wave functions were expanded by the double-numeric polarized (DNP) basis set [33,34]. The  $k$ -points of  $(3 \times 3 \times 1)$  was used to handle surface models. A smearing width of 0.005 Ha was used. The transition states of  $C_2H_2$  selective hydrogenation was obtained by the complete LST/QST technique [35,36]. TS confirmation and frequency analysis were implemented to confirm the structure of transition state.

### 2.2. Surface model

For the Cu IMCs, the  $Cu_xM_y$  ( $M = Pd, Pt, Au$ ) with Cu/M ratio of 3/1, 1/3 and 1/1 [37–39] are considered, while for the  $Cu_xM_y$  ( $M = Zn, Ni$ ), only the widely reported Cu/M ratios of 1/1 and 3/1 [24,40–44] are examined; the widely reported  $Cu_xAg_y$  corresponds to Cu/Ag ratio of 3/1 [41]. For the Pd IMCs,  $Pd_xN_y$  ( $N = Cu, Au$  and  $Ag$ ) with Pd/N ratio of 3/1, 1/3 and 1/1 are considered [37], while  $Pd_xN_y$  ( $N = Zn, Ga$ ) only considers the widely reported Pd/N ratio of 1/1 [27,45],  $Pd_xIn_y$  corresponds to Pd/In ratio of 1/1 and 3/1 [6,46],  $Pd_xSn_y$  corresponds to the ratio of 3/1 [47]. Further, in order to evaluate the catalytic performance of Cu IMCs and Pd IMCs catalysts in this study, Pd catalyst is selected as a reference. The optimized lattice parameters of Pd, Cu IMCs and Pd IMCs are summarized in Table S1, the calculated lattice parameters are close to the experimental values [27,37,39–41,43,46,47].

For the surface model, based on the low surface energy and dominantly exposed surface [6,27,43], the  $p(3 \times 3)$  (110) surface is selected for the  $Cu_1Zn_1$ , the  $p(3 \times 3)$  (111) surface is selected for the  $Cu_3Zn_1$ ,  $Cu_1Pt_1$ ,  $Cu_3Pt_1$ ,  $Cu_1Pt_3$ ,  $Cu_1Ni_1$ ,  $Cu_3Ni_1$ ,  $Cu_1Pd_1$ ,  $Cu_3Pd_1$ ,  $Cu_1Pd_3$ ,  $Cu_1Au_1$ ,  $Cu_3Au_1$ ,  $Cu_1Au_3$ ,  $Cu_3Ag_1$ ,  $Pd_1Zn_1$ ,  $Pd_3In_1$ ,  $Pd_3Sn_1$ ,  $Pd_1Ag_1$ ,  $Pd_3Ag_1$ ,  $Pd_1Ag_3$ ,  $Pd_1Au_1$ ,  $Pd_3Au_1$ ,  $Pd_1Au_3$  and Pd; the  $p(3 \times 2)$  (110) and  $p(4 \times 2)$  (110) surfaces are selected for  $Pd_1Ga_1$  and  $Pd_1In_1$  IMCs, respectively. All catalysts contain four atomic layers except for PdGa(110) with seven atomic layers. The bottom two layers for all surfaces are fixed except for PdGa(110) surface with the bottom four layers fixed. A vacuum region of 15 Å is set to

separate the periodic slabs. Fig. 1 shows the optimized model surfaces of Cu IMCs, Pd IMCs and Pd.

## 3. Results and discussion

### 3.1. The possible routes of $C_2H_2$ selective hydrogenation

As shown in Fig. 2,  $C_2H_2$  selective hydrogenation includes the processes of the hydrogenation and polymerization. For the hydrogenation process, three possible routes exist, the first is  **$C_2H_4$  desorption route** that  $C_2H_2(ad)$  is firstly hydrogenated via  $C_2H_3(ad)$  intermediate to generate  $C_2H_4(ad)$ , followed by its desorption from the catalyst surface; the second is  **$C_2H_4$  hydrogenation route** that  $C_2H_2(ad)$  is excessively hydrogenated to  $C_2H_5(ad)$  through  $C_2H_4$  intermediate; the third is  **$CHCH_3$  hydrogenation route** that  $C_2H_2(ad)$  is excessively hydrogenated to  $C_2H_5(ad)$  through  $CHCH_3$  intermediate. The route of  $C_2H_4$  desorption is the desired route to realize the removal of trace  $C_2H_2$  in rich- $C_2H_4$  stream.

Based on above analysis, the first is to determine the preference between  $C_2H_4$  hydrogenation and its desorption by comparing the activation free energy between  $C_2H_4$  hydrogenation and its desorption. Then, when  $C_2H_4$  desorption route is favored, starting from the common intermediate  $C_2H_3$  in three routes, the preference between  $C_2H_4$  formation and  $CHCH_3$  formation is examined. Finally, the catalysts that can produce gaseous  $C_2H_4$  are screened out.

For the polymerization process, green oil is formed to block active centers and deactivate the catalysts. Most studies have shown that the precursor for the production of green oil is 1,3-butadiene [1,2,48], thus, three possible routes of 1,3-butadiene formation are investigated, the first is the coupling of adsorbed  $C_2H_2$  to  $C_4H_4$ , followed by its hydrogenation to  $C_4H_6$ ; the second is the coupling of adsorbed  $C_2H_2$  and  $C_2H_3$  to  $C_4H_5$ , followed by its hydrogenation to  $C_4H_6$ ; the third is the coupling of adsorbed  $C_2H_3$  to  $C_4H_6$ .

### 3.2. $C_2H_2$ selective hydrogenation on the Cu IMCs catalysts

#### 3.2.1. The adsorption of $C_2H_2$ and $C_2H_4$

Since the amount of  $C_2H_2$  in the  $C_2H_4$ -rich stream is very small,  $C_2H_2$  must be strongly adsorbed on the catalyst than  $C_2H_4$  to ensure the subsequent hydrogenation of  $C_2H_2$ . The most stable configurations of  $C_2H_2$  and  $C_2H_4$  on the  $Cu_xM_y$  ( $M = Zn, Pt, Ni, Pd, Au$  and  $Ag$ ) IMCs are shown in Fig. S2.

As shown in Fig. 3a, on the  $Cu_1Au_1$  and  $Cu_1Au_3$  IMCs, the adsorption strength of  $C_2H_2$  (37.2 and 16.1  $\text{kJ}\cdot\text{mol}^{-1}$ ) and  $C_2H_4$  (1.1 and 1.9  $\text{kJ}\cdot\text{mol}^{-1}$ ) is very weak physisorption, namely, both  $Cu_1Au_1$  and  $Cu_1Au_3$  cannot validly adsorb trace  $C_2H_2$  in rich- $C_2H_4$  stream, and therefore  $C_2H_2$  selective hydrogenation cannot be performed. However,  $C_2H_2$  has much higher adsorption energy at 425 K than  $C_2H_4$  on other twelve types of Cu IMCs catalysts, including  $Cu_1Zn_1$ ,  $Cu_3Zn_1$ ,  $Cu_1Pt_1$ ,  $Cu_3Pt_1$ ,  $Cu_1Pt_3$ ,  $Cu_1Ni_1$ ,  $Cu_3Ni_1$ ,  $Cu_1Pd_1$ ,  $Cu_3Pd_1$ ,  $Cu_1Pd_3$ ,  $Cu_3Au_1$  and  $Cu_3Ag_1$ , indicating that these twelve types of Cu IMCs catalysts favor  $C_2H_2$  selective hydrogenation. Further, the adsorption energies and the stable configurations at 425 K of H,  $C_2H_3$ ,  $CHCH_3$  and  $C_2H_5$  species on twelve types of Cu IMCs are presented in Table S2 and Fig. S3.

#### 3.2.2. The preference between $C_2H_4$ desorption and its hydrogenation

Based on above analysis, the preference between  $C_2H_4$  hydrogenation and  $C_2H_4$  desorption is further examined on above twelve types of Cu IMCs catalysts, as shown in Fig. 4. Among them, only on  $Cu_1Pt_3$ ,  $C_2H_4$  desorption is competitive with its hydrogenation (80.2 vs. 87.4  $\text{kJ}\cdot\text{mol}^{-1}$ , Fig. 4e); whereas  $C_2H_4$  prefers to desorb rather than its hydrogenation to  $C_2H_5$  on other eleven types of Cu IMCs catalysts, including  $Cu_1Zn_1$ ,  $Cu_3Zn_1$ ,  $Cu_1Pt_1$ ,  $Cu_3Pt_1$ ,  $Cu_1Ni_1$ ,  $Cu_3Ni_1$ ,  $Cu_1Pd_1$ ,  $Cu_3Pd_1$ ,  $Cu_1Pd_3$ ,  $Cu_3Au_1$  and  $Cu_3Ag_1$ . Further, previous studies by Xu *et al.* [37] also showed that  $C_2H_4$  desorption prefers to occur rather than its hydrogenation over the three-layers  $p(4 \times 4)$  (111) surfaces of  $Cu_1Pt_1$  and  $Cu_3Pt_1$  IMCs at 473 K;

Fig. 1. The optimized surface structures of  $\text{Cu}_x\text{M}_y$  ( $M = \text{Zn, Pt, Ni, Pd, Au, Ag}$ ),  $\text{Pd}_x\text{N}_y$  ( $N = \text{Zn, Ga, In, Sn, Cu, Ag, Au}$ ) IMCs and Pd catalysts.

Fig. 2. The possible reaction pathways of  $\text{C}_2\text{H}_2$  selective hydrogenation including the hydrogenation and polymerization processes. (ad) stands for the adsorbed state, and (g) stands for the gas phase state, respectively.

the same results are also obtained by Wang *et al.* [49] on the three-layer  $p(3 \times 3)$  (111) surfaces of  $\text{Cu}_1\text{Pd}_1$ ,  $\text{Cu}_3\text{Pd}_1$  and  $\text{Cu}_1\text{Pd}_3$  IMCs at 400 K. Liu *et al.* [22] experimentally showed that the homogeneous CuNi alloy is in favor of gaseous  $\text{C}_2\text{H}_4$  formation.

### 3.2.3. The preference between $\text{C}_2\text{H}_4$ formation and $\text{CHCH}_3$ formation

As mentioned above, except for  $\text{Cu}_1\text{Pt}_3$  IMCs, other eleven types of Cu IMCs are conducive to  $\text{C}_2\text{H}_4$  desorption rather than being hydrogenated. Thus, starting from the common intermediate  $\text{C}_2\text{H}_3$  in three routes, we

**Fig. 3.** The adsorption free energies of C<sub>2</sub>H<sub>2</sub> and C<sub>2</sub>H<sub>4</sub> species over the (a) Cu<sub>x</sub>M<sub>y</sub> (M = Zn, Pt, Ni, Pd, Au, Ag) and (b) Pd<sub>x</sub>N<sub>y</sub> (N = Zn, Ga, In, Sn, Ag, Au) IMCs and Pd catalysts at 425 K.

further determine whether C<sub>2</sub>H<sub>4</sub> is more easily formed than CHCH<sub>3</sub> in C<sub>2</sub>H<sub>3</sub> hydrogenation (see Figs. S4–S8).

For the Cu<sub>x</sub>Zn<sub>y</sub> IMCs, C<sub>2</sub>H<sub>3</sub> hydrogenation to C<sub>2</sub>H<sub>4</sub> is kinetically more favorable than its hydrogenation to CHCH<sub>3</sub> on the Cu<sub>1</sub>Zn<sub>1</sub> (40.8 vs. 180.6 kJ·mol<sup>-1</sup>, Fig. S4a) and Cu<sub>3</sub>Zn<sub>1</sub> (65.6 vs. 204.7 kJ·mol<sup>-1</sup>, Fig. S4b). The same thing also occurs on the Cu<sub>1</sub>Pt<sub>1</sub>, Cu<sub>3</sub>Pt<sub>1</sub>, Cu<sub>1</sub>Ni<sub>1</sub>, Cu<sub>3</sub>Ni<sub>1</sub>, Cu<sub>1</sub>Pd<sub>1</sub>, Cu<sub>3</sub>Pd<sub>1</sub>, Cu<sub>3</sub>Au<sub>1</sub> and Cu<sub>3</sub>Ag<sub>1</sub>, as presented in Figs. S5–S8. However, it is opposite on Cu<sub>1</sub>Pd<sub>3</sub> (109.4 vs. 94.4 kJ·mol<sup>-1</sup>, Fig. S7c), while CHCH<sub>3</sub> hydrogenation to C<sub>2</sub>H<sub>5</sub> is more difficult compared to C<sub>2</sub>H<sub>4</sub> formation and desorption (170.4 vs. 109.4 kJ·mol<sup>-1</sup>, Fig. S7c), thus, CHCH<sub>3</sub> hydrogenation route is unfavorable on Cu<sub>1</sub>Pd<sub>3</sub>, which agree with

the previous work by Wang *et al.* [49] on the three-layer  $p(3 \times 3)$  (111) surfaces of Cu<sub>1</sub>Pd<sub>1</sub>, Cu<sub>3</sub>Pd<sub>1</sub> and Cu<sub>1</sub>Pd<sub>3</sub> IMCs at 400 K.

Above results show that eleven types of Cu IMCs, including Cu<sub>1</sub>Zn<sub>1</sub>, Cu<sub>3</sub>Zn<sub>1</sub>, Cu<sub>1</sub>Pt<sub>1</sub>, Cu<sub>3</sub>Pt<sub>1</sub>, Cu<sub>1</sub>Ni<sub>1</sub>, Cu<sub>3</sub>Ni<sub>1</sub>, Cu<sub>1</sub>Pd<sub>1</sub>, Cu<sub>3</sub>Pd<sub>1</sub>, Cu<sub>3</sub>Au<sub>1</sub>, Cu<sub>3</sub>Ag<sub>1</sub> and Cu<sub>1</sub>Pd<sub>3</sub>, preferentially favor C<sub>2</sub>H<sub>2</sub> hydrogenation to C<sub>2</sub>H<sub>4</sub> and its subsequent desorption. Namely, C<sub>2</sub>H<sub>4</sub> desorption route to produce gaseous C<sub>2</sub>H<sub>4</sub> is dominant.

### 3.2.4. C<sub>2</sub>H<sub>4</sub> formation activity and selectivity

Since eleven types of Cu<sub>x</sub>M<sub>y</sub> (M = Zn, Pt, Ni, Pd, Au and Ag) IMCs favor the production of gaseous C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>4</sub> formation activity and selectivity

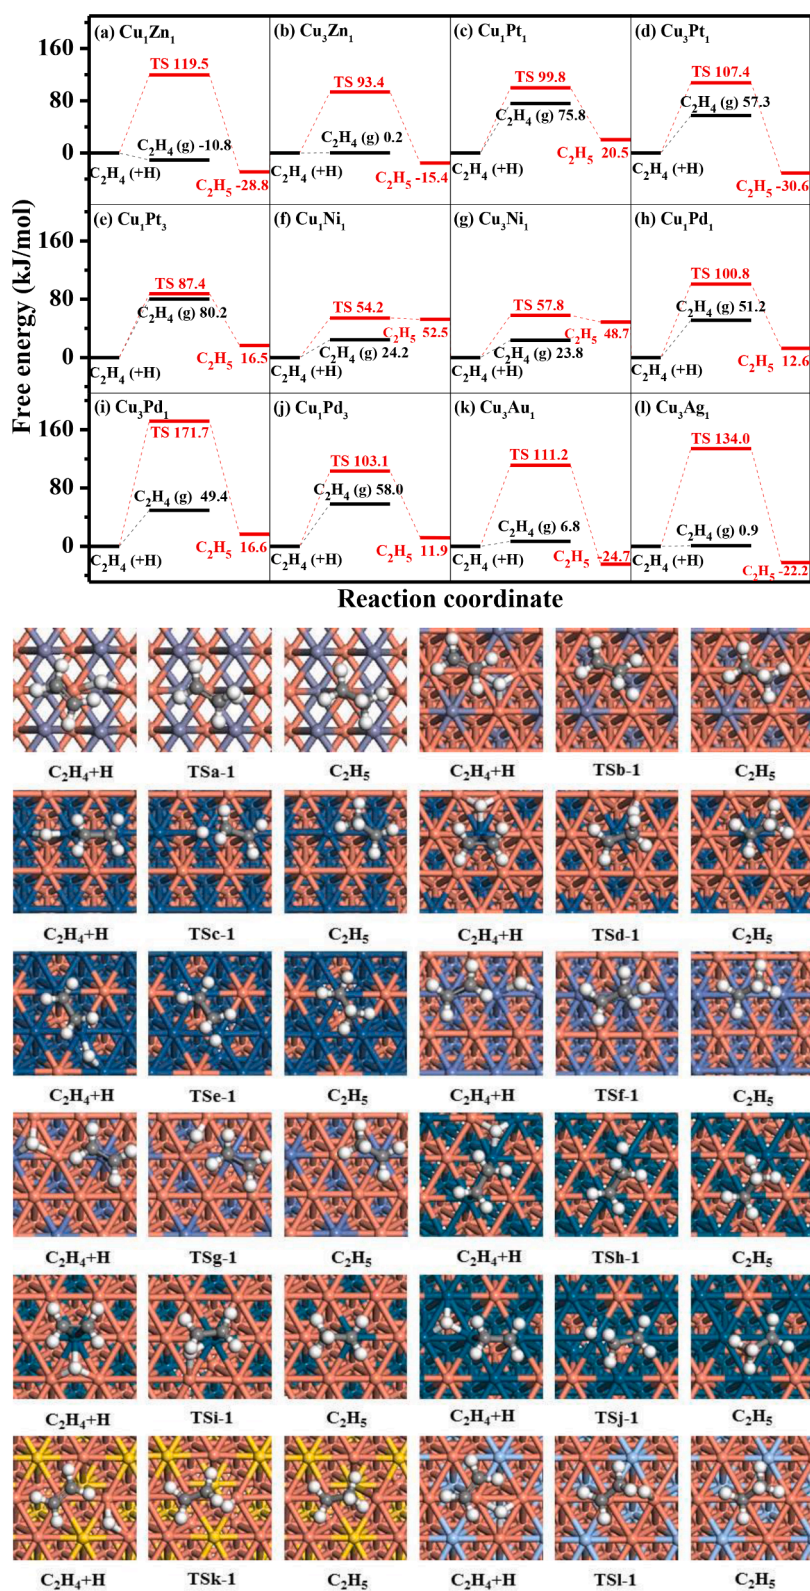

Fig. 4. The potential energy profile at 425 K of  $C_2H_4$  hydrogenation and  $C_2H_4$  desorption together with the initial state, transition state and final state on the (a)  $Cu_1Zn_1$ , (b)  $Cu_3Zn_1$ , (c)  $Cu_1Pt_1$ , (d)  $Cu_3Pt_1$ , (e)  $Cu_1Pt_3$ , (f)  $Cu_1Ni_1$ , (g)  $Cu_3Ni_1$ , (h)  $Cu_1Pd_1$ , (i)  $Cu_3Pd_1$ , (j)  $Cu_1Pd_3$ , (k)  $Cu_3Au_1$  and (l)  $Cu_3Ag_1$ , respectively.

over these catalysts are calculated to evaluate the catalytic performance [37,50,51].

In this study, the descriptor, the energy difference between  $C_2H_4$  hydrogenation and its desorption, is used to evaluate  $C_2H_4$  selectivity, this descriptor as the simplest way can well quantitatively and qualitatively

evaluate  $C_2H_4$  selectivity in  $C_2H_2$  selective hydrogenation, which has been widely used in the previous studies by Hu *et al.* [8,51–54], Mavrikakis *et al.* [37], Celik *et al.* [55], Hafner *et al.* [56], Kang *et al.* [18], Wang *et al.* [57,58] and Gong *et al.* [1], the obtained results can well present  $C_2H_4$  selectivity over the reported catalysts and agrees with the experimental

results. Meanwhile,  $C_2H_4$  formation rate is calculated to evaluate  $C_2H_4$  formation activity [59,60], which is calculated according to a two-step model [8,61] under the typically experimental conditions ( $T = 425$  K,  $P = 1$  atm; the partial pressure of  $C_2H_2$ ,  $H_2$  and  $C_2H_4$  correspond to 0.01, 0.1 and 0.89 atm, respectively) (the details are presented in the Supplementary Material).

As listed in Table 1, eleven types of Cu IMCs catalysts correspond to  $C_2H_4$  selectivity of 130.3, 93.2, 24.0, 50.1, 30.0, 34.0, 49.6, **122.3**, 45.1, 104.4 and 133.1  $\text{kJ}\cdot\text{mol}^{-1}$ ; correspondingly,  $C_2H_4$  formation activity of  $1.21 \times 10^{-4}$ ,  $5.27 \times 10^{-1}$ ,  $8.85 \times 10^1$ ,  $8.08 \times 10^{-4}$ ,  $8.87 \times 10^{-2}$ ,  $1.33 \times 10^1$ ,  $2.30 \times 10^{-3}$ ,  **$4.77 \times 10^6$** ,  $3.17 \times 10^{-1}$ ,  $4.45 \times 10^{-4}$  and  $5.68 \times 10^0$   $\text{s}^{-1}\cdot\text{site}^{-1}$  on the  $Cu_1Zn_1$ ,  $Cu_3Zn_1$ ,  $Cu_1Pt_1$ ,  $Cu_3Pt_1$ ,  $Cu_1Ni_1$ ,  $Cu_3Ni_1$ ,  $Cu_1Pd_1$ ,  $Cu_3Pd_1$ ,  $Cu_1Pd_3$ ,  $Cu_3Au_1$  and  $Cu_3Ag_1$ , respectively.

Above results show that  $Cu_3Pd_1$  with the isolated single-atom Pd as active center exhibits outstanding  $C_2H_4$  selectivity and activity (**122.3**  $\text{kJ}\cdot\text{mol}^{-1}$  and  **$4.77 \times 10^6$**   $\text{s}^{-1}\cdot\text{site}^{-1}$ ). Hence,  $Cu_3Pd_1$  can better promote  $C_2H_4$  formation.

### 3.2.5. The influences of partner metal ratio and metal type on $C_2H_4$ formation

Based on above results, among  $Cu_xM_y$  ( $M = \text{Zn, Pt, Ni, Pd, Au and Ag}$ ) IMCs, the  $Cu_xPd_y$ ,  $Cu_xAg_y$ ,  $Cu_xAu_y$  and  $Cu_xNi_y$  IMCs corresponding to Cu/Pd, Cu/Ag, Cu/Au and Cu/Ni ratio of 3/1 have better  $C_2H_4$  formation activity and selectivity than the other Cu/M ( $M = \text{Pd, Ag, Au and Ni}$ ) ratios; however, the  $Cu_xZn_y$  with the Cu/Zn ratio of 3/1 and  $Cu_xPt_y$  with the Cu/Pt ratio of 1/1 have high activity of  $C_2H_4$  formation, whereas the  $Cu_xZn_y$  with the Cu/Zn ratio of 1/1 and  $Cu_xPt_y$  with the Cu/Pt ratio of 3/1 have high  $C_2H_4$  selectivity. Thus, the partner metal ratio of  $Cu_xM_y$  ( $M = \text{Zn, Pt, Ni, Pd, Au and Ag}$ ) IMCs has a significant influence on  $C_2H_4$  formation activity and selectivity. In addition, NiGa IMCs has better activity and selectivity than Ni and  $Ni_3Ga$  IMCs for  $C_2H_2$  selective hydrogenation to  $C_2H_4$  [23]. PdIn presented better selectivity than  $Pd_3In$  and Pd for HCOOH oxidation [62].  $Ni_3Sn_2$  displays the best furfuryl alcohol selectivity and its formation activity for furfural selective

**Table 1**

The calculated adsorption free energies ( $G_{\text{ads}}/\text{kJ}\cdot\text{mol}^{-1}$ ) of  $C_2H_2$  and  $C_2H_4$ , the activation barriers ( $G_a/\text{kJ}\cdot\text{mol}^{-1}$ ) of  $C_2H_4$  hydrogenation to  $C_2H_5$ ,  $C_2H_4$  selectivity ( $G_{\text{sel}}/\text{kJ}\cdot\text{mol}^{-1}$ ) and the reaction rate of  $C_2H_4$  formation ( $r/\text{s}^{-1}\cdot\text{site}^{-1}$ ) in  $C_2H_2$  selective hydrogenation over the  $Cu_xM_y$  and  $Pd_xN_y$  IMCs and Pd catalysts at 425 K except for the  $Cu_1Au_1$ ,  $Cu_1Au_3$ ,  $Pd_1Ag_3$  and  $Pd_1Au_3$  catalysts that cannot achieve effective adsorption of trace  $C_2H_2$  in  $C_2H_4$ -rich streams, and  $Cu_1Pt_3$  catalyst with  $C_2H_4$  desorption competitive with its hydrogenation.

Catalysts	$G_{\text{ads}}(C_2H_2)$	$G_{\text{ads}}(C_2H_4)$	$G_a$	$G_{\text{sel}}$	$r$

hydrogenation on the  $Ni_3Sn_1$ ,  $Ni_3Sn_2$  and  $Ni_3Sn_4$  IMCs [63]. Further, as shown in Fig. 6, the partner metal type M ( $M = \text{Zn, Pt, Ni, Pd, Au and Ag}$ ) in the  $Cu_xM_y$  IMCs catalysts affects  $C_2H_4$  formation activity and selectivity, among them,  $Cu_3Pd_1$  catalyst displays remarkably high  $C_2H_4$  formation activity and selectivity compared to other  $Cu_xM_y$  IMCs catalysts, suggesting that  $Cu_3Pd_1$  IMCs doped the partner metal Pd into Cu is the best choice for  $C_2H_2$  selective hydrogenation among  $Cu_xM_y$  IMCs. In addition, CuNi(111) is more favorable for carbon elimination than FeNi(111) and Ni(111) [40]. Wang et al. [49] found that PdCu<sub>3</sub> displays the highest  $C_2H_4$  formation activity and selectivity among PdCu, PdAg and PdAu IMCs.

### 3.3. $C_2H_2$ selective hydrogenation on the Pd IMCs catalysts

#### 3.3.1. The adsorption of $C_2H_2$ and $C_2H_4$

Similar to Cu IMCs, the adsorptions of  $C_2H_2$  and  $C_2H_4$  on the  $Pd_xN_y$  ( $N = \text{Zn, Ga, In, Sn, Cu, Ag and Au}$ ) IMCs and Pd catalysts are examined (see details in Fig. S2). As shown in Fig. 3b, the adsorption free energy of  $C_2H_2$  and  $C_2H_4$  on the  $Pd_1Ag_3$  (52.6 and 43.0  $\text{kJ}\cdot\text{mol}^{-1}$ ) and  $Pd_1Au_3$  (50.5 and 42.5  $\text{kJ}\cdot\text{mol}^{-1}$ ) is very close, which is not in favor of the effective adsorption of the trace  $C_2H_2$  in a large amount of  $C_2H_4$ . However,  $C_2H_2$  has much larger adsorption energy than  $C_2H_4$  on the  $Pd_1Zn_1$ ,  $Pd_1Ga_1$ ,  $Pd_1In_1$ ,  $Pd_3In_1$ ,  $Pd_3Sn_1$ ,  $Pd_1Cu_1$ ,  $Pd_3Cu_1$ ,  $Pd_1Cu_3$ ,  $Pd_1Ag_1$ ,  $Pd_3Ag_1$ ,  $Pd_1Au_1$ ,  $Pd_3Au_1$  and Pd at 425 K. Namely,  $C_2H_2$  is more strongly adsorbed than  $C_2H_4$  on above twelve types of Pd IMCs and Pd catalysts. Correspondingly, the adsorption energies and stable adsorption configurations at 425 K of H,  $C_2H_3$ , CHCH<sub>3</sub> and  $C_2H_5$  species on twelve types of Pd IMCs and Pd catalysts are presented in Table S2 and Fig. S3.

#### 3.3.2. The preference between $C_2H_4$ desorption and its hydrogenation

As mentioned above, the preference between  $C_2H_4$  hydrogenation and its desorption is further examined on twelve types of Pd IMCs and Pd. As presented in Fig. 5,  $C_2H_4$  desorption occurs more easily compared to its hydrogenation on the  $Pd_1Zn_1$ ,  $Pd_1Ga_1$ ,  $Pd_1In_1$ ,  $Pd_3In_1$ ,  $Pd_3Sn_1$ ,  $Pd_1Ag_1$ ,  $Pd_3Ag_1$ ,  $Pd_1Au_1$ ,  $Pd_3Au_1$  and Pd. The same thing also occurs on the  $Pd_1Cu_1$  (Fig. 4h),  $Pd_1Cu_3$  (Fig. 4i) and  $Pd_3Cu_1$  (Fig. 4j). Thus, the desorption of  $C_2H_4$  is more favorable on these twelve types of Pd IMCs and Pd catalyst. Previous studies also showed that  $C_2H_4$  desorption (48.0  $\text{kJ}\cdot\text{mol}^{-1}$ ) is easier than its hydrogenation (84.0  $\text{kJ}\cdot\text{mol}^{-1}$ ) on PdZn(100) IMCs at 0 K [20]; the same results also occur on the three-layer  $p(3 \times 3)$  (111) surfaces of  $Pd_1Ag_1$ ,  $Pd_3Ag_1$ ,  $Pd_1Au_1$  and  $Pd_3Au_1$  IMCs at 400 K [49].

#### 3.3.3. The preference between $C_2H_4$ formation and CHCH<sub>3</sub> formation

For the  $Pd_xN_y$  IMCs (see Figs. S9–S14),  $C_2H_3$  is preferentially hydrogenated to generate  $C_2H_4$  rather than CHCH<sub>3</sub> on the  $Pd_1Zn_1$  (Fig. S9a),  $Pd_1Ga_1$  (Fig. S9b),  $Pd_1In_1$  (Fig. S10a),  $Pd_3In_1$  (Fig. S10b),  $Pd_3Sn_1$  (Fig. S11),  $Pd_1Ag_1$  (Fig. S12a) and  $Pd_1Au_1$  (Fig. S13a); the same thing also occurs on the  $Pd_1Cu_1$  (Fig. S7a) and  $Pd_1Cu_3$  (Fig. S7b). On the other hand, it is opposite on the  $Pd_3Cu_1$  (Fig. S7c),  $Pd_3Ag_1$  (Fig. S12b),  $Pd_3Au_1$  (Fig. S13b) and Pd (Fig. S14), however, CHCH<sub>3</sub> hydrogenation to  $C_2H_5$  is more difficult than  $C_2H_4$  formation and desorption on the  $Pd_3Cu_1$  (170.4 vs. 109.4  $\text{kJ}\cdot\text{mol}^{-1}$ , Fig. S7c),  $Pd_3Ag_1$  (173.7 vs. 131.6  $\text{kJ}\cdot\text{mol}^{-1}$ , Fig. S12b),  $Pd_3Au_1$  (89.7 vs. 83.3  $\text{kJ}\cdot\text{mol}^{-1}$ , Fig. S13b) and Pd (126.9 vs. 109.0  $\text{kJ}\cdot\text{mol}^{-1}$ , Fig. S14), thus, CHCH<sub>3</sub> hydrogenation route is not easy to occur.

Above results show that  $C_2H_3$  hydrogenation to  $C_2H_4$  and  $C_2H_4$  desorption are favored on above twelve types of Pd IMCs and Pd catalysts, namely,  $C_2H_4$  desorption route to form gaseous  $C_2H_4$  is dominant among three hydrogenation routes.

#### 3.3.4. $C_2H_4$ formation activity and selectivity

As illustrated in Table 1, on twelve types of  $Pd_xN_y$  ( $N = \text{Zn, Ga, In, Sn, Cu, Ag and Au}$ ) IMCs and Pd catalysts,  $C_2H_4$  selectivity is 83.6, 162.7, 217.0, 115.0, 125.6, 49.6, 45.1, **122.3**, 44.1, 60.1, 36.0, 29.5 and 18.9  $\text{kJ}\cdot\text{mol}^{-1}$  on the  $Pd_1Zn_1$ ,  $Pd_1Ga_1$ ,  $Pd_1In_1$ ,  $Pd_3In_1$ ,  $Pd_3Sn_1$ ,  $Pd_1Cu_1$ ,  $Pd_3Cu_1$ ,  $Pd_1Cu_3$ ,  $Pd_1Ag_1$ ,  $Pd_3Ag_1$ ,  $Pd_1Au_1$ ,  $Pd_3Au_1$  and Pd catalysts.

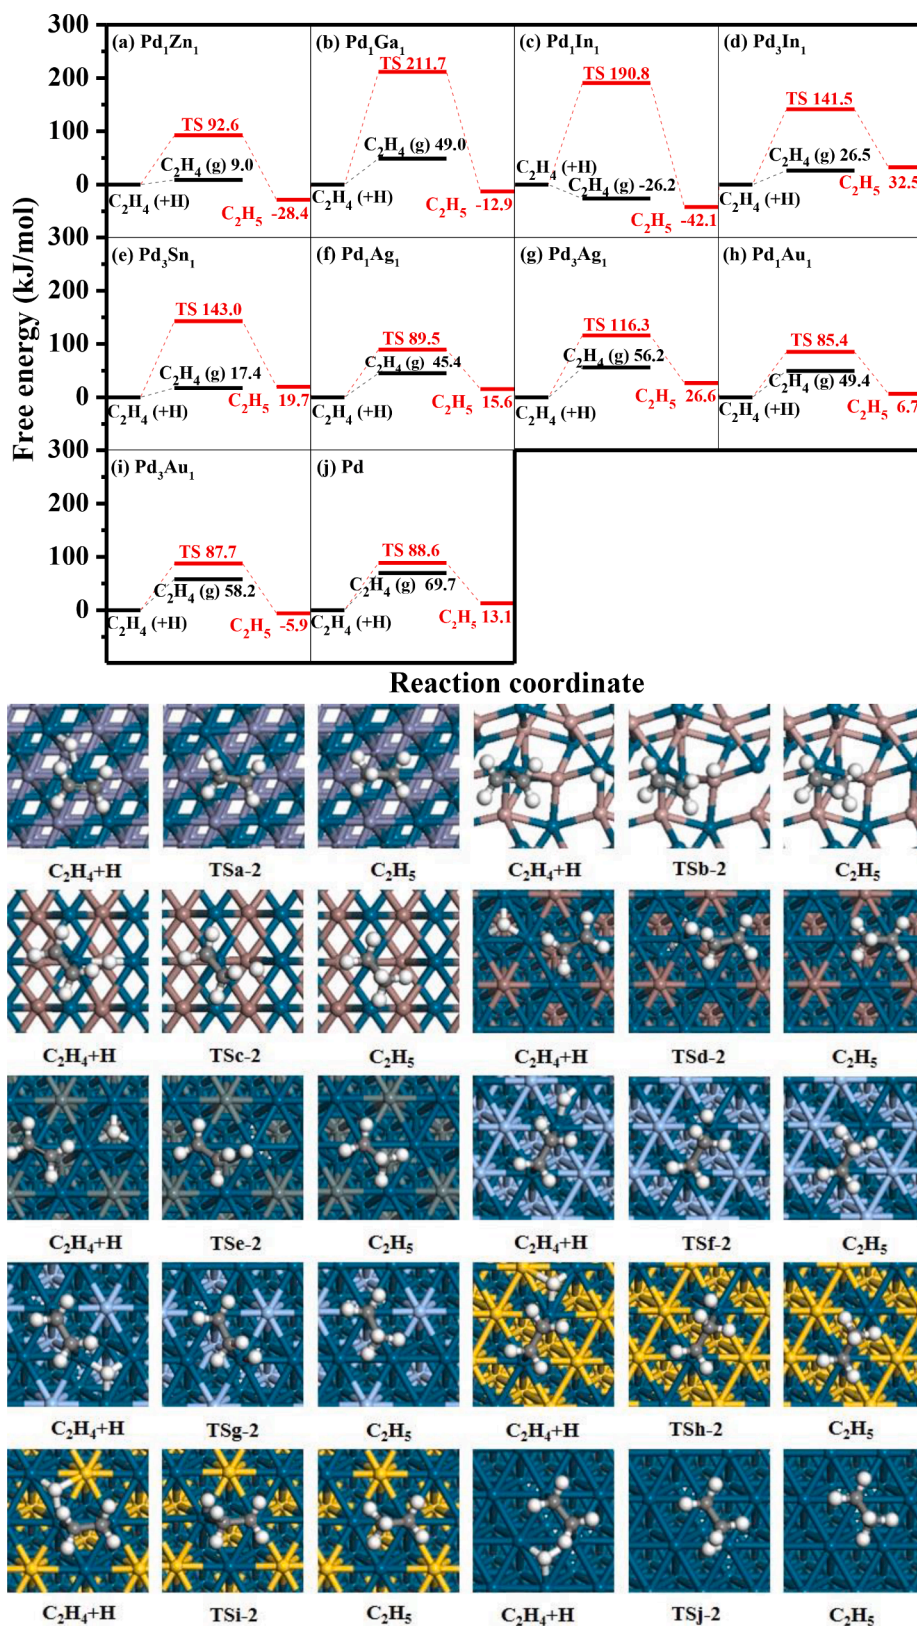

Fig. 5. The potential energy profile at 425 K of C<sub>2</sub>H<sub>4</sub> hydrogenation and C<sub>2</sub>H<sub>4</sub> desorption with the initial state, transition state and final state on the (a) Pd<sub>1</sub>Zn<sub>1</sub>, (b) Pd<sub>1</sub>Ga<sub>1</sub>, (c) Pd<sub>1</sub>In<sub>1</sub>, (d) Pd<sub>3</sub>In<sub>1</sub>, (e) Pd<sub>3</sub>Sn<sub>1</sub>, (f) Pd<sub>1</sub>Ag<sub>1</sub>, (g) Pd<sub>3</sub>Ag<sub>1</sub>, (h) Pd<sub>1</sub>Au<sub>1</sub>, (i) Pd<sub>3</sub>Au<sub>1</sub> and (j) Pd, respectively.

Correspondingly,  $C_2H_4$  formation activity is  $2.57 \times 10^0$ ,  $1.20 \times 10^{-3}$ ,  $2.05 \times 10^0$ ,  $1.23 \times 10^{-5}$ ,  $9.38 \times 10^{-2}$ ,  $2.30 \times 10^{-3}$ ,  $3.17 \times 10^{-1}$ ,  $4.77 \times 10^6$ ,  $4.41 \times 10^0$ ,  $5.92 \times 10^{-4}$ ,  $3.01 \times 10^4$ ,  $5.12 \times 10^2$  and  $3.55 \times 10^{-1} \text{ s}^{-1} \cdot \text{site}^{-1}$ , respectively. Thus, among the  $Pd_xN_y$  IMCs,  $Pd_1Cu_3$  IMCs with the surface single-atom Pd as active center presents outstanding selectivity and activity ( $122.3 \text{ kJ} \cdot \text{mol}^{-1}$  and  $4.77 \times 10^6 \cdot \text{s}^{-1} \cdot \text{site}^{-1}$ ) for gaseous  $C_2H_4$  formation.

### 3.3.5. The influences of partner metal ratio and metal type on $C_2H_4$ formation

Similarly, the influences of partner metal ratio and type in the  $Pd_xN_y$  ( $N = \text{Zn, Ga, In, Sn, Cu, Ag}$  and  $\text{Au}$ ) IMCs on  $C_2H_4$  formation activity and selectivity are also obvious. Among them, the  $Pd_xIn_y$ ,  $Pd_xAg_y$  and  $Pd_xAu_y$  IMCs corresponding to Pd/In, Pd/Ag and Pd/Au ratio of 1/1 have superior  $C_2H_4$  formation activity and selectivity than other Pd/N ( $N = \text{In, Ag}$  and  $\text{Au}$ ) ratios. Similarly, the  $Pd_xZn_y$  and  $Pd_xGa_y$  IMCs also correspond to the Pd/Zn or Pd/Ga ratio of 1/1. However,  $Pd_xSn_y$  IMCs correspond to the Pd/Sn ratio of 3/1, and it is Pd/Cu ratio of 1/3 for  $Pd_xCu_y$  IMCs. Thus, the  $Pd_1Zn_1$ ,  $Pd_1Ga_1$ ,  $Pd_1In_1$ ,  $Pd_1Ag_1$ ,  $Pd_1Au_1$ ,  $Pd_3Sn_1$  and  $Pd_1Cu_3$  IMCs favor the formation of gaseous  $C_2H_4$ .

Moreover, as shown in Fig. 6, the partner metal type ( $N = \text{Zn, Ga, In, Sn, Cu, Ag}$  and  $\text{Au}$ ) in  $Pd_xN_y$  IMCs affects  $C_2H_4$  formation activity and selectivity, among them,  $Pd_1Cu_3$  IMCs displays the highest activity and superior selectivity for  $C_2H_4$  formation compared to other six types of  $Pd_xN_y$  IMCs catalysts, namely,  $Pd_1Cu_3$  IMCs becomes the best choice for  $C_2H_2$  selective hydrogenation among  $Pd_xN_y$  IMCs.

## 3.4. General discussions

### 3.4.1. The influences of partner metal ratio and type on $C_2H_4$ formation activity and selectivity

Noble-metal Pd has been industrially used to remove trace  $C_2H_2$  from a large amount of  $C_2H_4$  due to its high hydrogenation activity [8,64], aiming at obtaining the influences of partner metal ratio and type in the  $Cu_xM_y$  or  $Pd_xN_y$  IMCs on  $C_2H_4$  formation activity and selectivity, the comparisons of the activity and selectivity between  $Cu_xM_y/Pd_xN_y$  IMCs and Pd catalysts are carried out.

For the  $Cu_xM_y$  IMCs, all considered catalysts exhibit better  $C_2H_4$  selectivity ( $\text{kJ} \cdot \text{mol}^{-1}$ ) compared to Pd catalyst, following the order of  $Cu_3Ag_1(133.1) > Cu_1Zn_1(130.3) > Cu_3Pd_1(122.3) > Cu_3Au_1(104.4) > Cu_3Zn_1(93.2) > Cu_3Pt_1(50.1) > Cu_1Pd_1(49.6) > Cu_1Pd_3(45.1) > Cu_3Ni_1(34.0) > Cu_1Ni_1(30.0) > Cu_1Pt_1(24.0) > Pd(18.9)$ . The activity ( $\text{s}^{-1} \cdot \text{site}^{-1}$ ) of  $C_2H_4$  formation on the  $Cu_3Pd_1$ ,  $Cu_1Pt_1$ ,  $Cu_3Ni_1$ ,  $Cu_3Ag_1$  and  $Cu_3Zn_1$  ( $4.77 \times 10^6$ ,  $8.85 \times 10^1$ ,  $1.33 \times 10^1$ ,  $5.68 \times 10^0$  and  $5.27 \times 10^{-1}$ ) is superior to that on Pd catalyst ( $3.55 \times 10^{-1}$ ). Thus,  $C_2H_4$  formation activity and selectivity on five types of  $Cu_3Zn_1$ ,  $Cu_1Pt_1$ ,  $Cu_3Ni_1$ ,  $Cu_3Pd_1$  and  $Cu_3Ag_1$  IMCs have a greater improvement compared to that on Pd catalyst. Among them,  $Cu_3Pd_1$  that has the surface single-atom Pd as active center displays outstanding  $C_2H_4$  formation activity and selectivity.

For the  $Pd_xN_y$  IMCs,  $C_2H_4$  selectivity ( $\text{kJ} \cdot \text{mol}^{-1}$ ) follows the order of  $Pd_1In_1(217.0) > Pd_1Ga_1(162.7) > Pd_3Sn_1(125.6) > Pd_1Cu_3(122.3) > Pd_3In_1(115.0) > Pd_1Zn_1(83.6) > Pd_3Ag_1(60.1) > Pd_1Cu_1(49.6) > Pd_3Cu_1(45.1) > Pd_1Ag_1(44.1) > Pd_1Au_1(36.0) > Pd_3Au_1(29.5) > Pd(18.9)$ . The activity ( $\text{s}^{-1} \cdot \text{site}^{-1}$ ) of  $C_2H_4$  formation on the  $Pd_1Cu_3$ ,  $Pd_1Au_1$ ,  $Pd_3Au_1$ ,  $Pd_1Ag_1$ ,  $Pd_1Zn_1$  and  $Pd_1In_1$  ( $4.77 \times 10^6$ ,  $3.01 \times 10^4$ ,  $5.12 \times 10^2$ ,  $4.41 \times 10^0$ ,  $2.57 \times 10^0$  and  $2.05 \times 10^0$ ) is superior to that on Pd catalyst ( $3.55 \times 10^{-1}$ ). Namely,  $C_2H_4$  formation activity and selectivity on six types of  $Pd_1Cu_3$ ,  $Pd_1Au_1$ ,  $Pd_3Au_1$ ,  $Pd_1Ag_1$ ,  $Pd_1Zn_1$  and  $Pd_1In_1$  IMCs have been greatly improved in comparison with that on Pd catalyst, among them,  $Pd_1Cu_3$  IMCs corresponding to the isolated surface single-atom Pd active center exhibits excellent  $C_2H_4$  formation activity and selectivity.

In general, as presented in Fig. 6, among all considered  $Cu_xM_y$  or  $Pd_xN_y$  IMCs in this study,  $Pd_xCu_y$  IMCs that has the Pd/Cu ratio of 1:3 becomes the best choice for  $C_2H_2$  hydrogenation to produce gaseous  $C_2H_4$  with excellent activity and selectivity ( $4.77 \times 10^6 \text{ s}^{-1} \cdot \text{site}^{-1}$  and  $122.3 \text{ kJ} \cdot \text{mol}^{-1}$ ) in comparison with other  $Cu_xM_y$  or  $Pd_xN_y$  IMCs and Pd catalysts. Further, previous studies found that Cu exhibited low activity for alkyne hydrogenation [65,66]. The selectivity ( $13.0 \text{ kJ} \cdot \text{mol}^{-1}$ ) and activity ( $1.00 \times 10^{-2} \text{ s}^{-1} \cdot \text{site}^{-1}$ ) of  $C_2H_4$  formation on Cu catalyst at 425 K are much lower than those on  $Pd_1Cu_3$  IMCs [67]. Moreover, PdCu(111) alloy surface doped by the single-atom Pd displays  $C_2H_4$  selectivity of  $39.8 \text{ kJ} \cdot \text{mol}^{-1}$ , which is still much lower than

Fig. 6. (a)  $C_2H_4$  selectivity and (b)  $C_2H_4$  formation activity in  $C_2H_2$  selective hydrogenation over the  $Cu_xM_y$  ( $M = \text{Zn, Pt, Ni, Pd, Au, Ag}$ ) and  $Pd_xN_y$  ( $N = \text{Zn, Ga, In, Sn, Cu, Ag, Au}$ ) IMCs and Pd catalysts at 425 K.

that on Pd<sub>1</sub>Cu<sub>3</sub> IMCs [30]; meanwhile, PdCu(211) alloy surface doped by the single-atom Pd shows C<sub>2</sub>H<sub>4</sub> formation activity of  $1.58 \times 10^4$  s<sup>-1</sup>·site<sup>-1</sup> and its selectivity of 36.4 kJ·mol<sup>-1</sup> in C<sub>2</sub>H<sub>2</sub> selective hydrogenation [60], however, both are still much lower than those on Pd<sub>1</sub>Cu<sub>3</sub> IMCs catalyst in this study.

Further, Wang et al. [68] studied C<sub>2</sub>H<sub>2</sub> selective hydrogenation over the anatase and rutile supported Pd<sub>4</sub> cluster and found that the anatase one has higher C<sub>2</sub>H<sub>4</sub> selectivity than the rutile one due to the easier C<sub>2</sub>H<sub>4</sub> desorption and higher activation barriers of C<sub>2</sub>H<sub>4</sub> hydrogenation. Guan et al. [69] investigated C<sub>2</sub>H<sub>2</sub> selective hydrogenation over the supported Pd and Cu cluster with different supports, suggesting that the oxygen-vacancy anatase supported Pd<sub>19</sub> cluster is the most favorable for gaseous C<sub>2</sub>H<sub>4</sub> formation, but the activity ( $6.19 \times 10^5$  s<sup>-1</sup>·site<sup>-1</sup>) is still much lower than that of Pd<sub>1</sub>Cu<sub>3</sub> IMCs in our study. Meng et al. [57] reported C<sub>2</sub>H<sub>2</sub> selective hydrogenation over the oxygen defective anatase supported Pd<sub>4</sub> and Pd<sub>a</sub>Ag<sub>b</sub>(a + b = 4) clusters, indicating that the supported Pd<sub>3</sub>Ag cluster displays the highest C<sub>2</sub>H<sub>4</sub> selectivity (103.2 kJ·mol<sup>-1</sup>), which is still lower than that of Pd<sub>1</sub>Cu<sub>3</sub> IMCs in our study. Therefore, Pd<sub>1</sub>Cu<sub>3</sub> IMCs in this study is more favorable for C<sub>2</sub>H<sub>4</sub> formation to remove traces C<sub>2</sub>H<sub>2</sub> in comparison with the single Pd, Cu, the single-atom Pd-doped Cu alloy and the supported catalysts, which is attributed to well-defined surface atomic arrangement.

### 3.4.2. The influences of partner metal ratio and type on green oil production

Since the production of green oil can block active centers and deactivate the catalyst in C<sub>2</sub>H<sub>2</sub> selective hydrogenation, we further analyze the production of green oil over the Cu<sub>x</sub>M<sub>y</sub> or Pd<sub>x</sub>N<sub>y</sub> IMCs screened out based on better activity and selectivity toward C<sub>2</sub>H<sub>4</sub> formation in comparison with Pd catalyst.

For the Cu<sub>x</sub>M<sub>y</sub> IMCs, the production of green oil on five types of Cu<sub>3</sub>Zn<sub>1</sub>, Cu<sub>1</sub>Pt<sub>1</sub>, Cu<sub>3</sub>Ni<sub>1</sub>, Cu<sub>3</sub>Pd<sub>1</sub> and Cu<sub>3</sub>Ag<sub>1</sub> catalysts is investigated (see Fig. S15). On Cu<sub>3</sub>Zn<sub>1</sub>, see Fig. S15a, compared to the routes of C<sub>2</sub>H<sub>2</sub>+C<sub>2</sub>H<sub>2</sub> (212.9 kJ·mol<sup>-1</sup>) and C<sub>2</sub>H<sub>2</sub>+C<sub>2</sub>H<sub>3</sub> (238.9 kJ·mol<sup>-1</sup>), the route of C<sub>2</sub>H<sub>3</sub>+C<sub>2</sub>H<sub>3</sub> to produce 1,3-butadiene is the most advantageous in kinetics (141.7 kJ·mol<sup>-1</sup>). The same thing also occurs on the Cu<sub>3</sub>Pd<sub>1</sub>, Cu<sub>3</sub>Ag<sub>1</sub>, Cu<sub>1</sub>Pt<sub>1</sub> and Cu<sub>3</sub>Ni<sub>1</sub> (see Figs. S15b~S15e). Further, as presented in Fig. 7,

the route of C<sub>2</sub>H<sub>3</sub>+C<sub>2</sub>H<sub>3</sub> to 1,3-butadiene is much easier in kinetics than C<sub>2</sub>H<sub>4</sub> desorption route on the Cu<sub>1</sub>Pt<sub>1</sub> (74.2 vs. 76.7 kJ·mol<sup>-1</sup>) and Cu<sub>3</sub>Ni<sub>1</sub> (23.9 vs. 32.8 kJ·mol<sup>-1</sup>), respectively. However, C<sub>2</sub>H<sub>4</sub> desorption route is much easier in kinetics than the route of C<sub>2</sub>H<sub>3</sub>+C<sub>2</sub>H<sub>3</sub> to 1,3-butadiene on the Cu<sub>3</sub>Zn<sub>1</sub> (98.5 vs. 174.6 kJ·mol<sup>-1</sup>), Cu<sub>3</sub>Pd<sub>1</sub> (46.2 vs. 61.9 kJ·mol<sup>-1</sup>) and Cu<sub>3</sub>Ag<sub>1</sub> (102.7 vs. 162.2 kJ·mol<sup>-1</sup>). Thus, green oil is easily produced on the Cu<sub>1</sub>Pt<sub>1</sub> and Cu<sub>3</sub>Ni<sub>1</sub>, whereas Cu<sub>3</sub>Zn<sub>1</sub>, Cu<sub>3</sub>Pd<sub>1</sub> and Cu<sub>3</sub>Ag<sub>1</sub> can validly suppress green oil production.

For the Pd<sub>x</sub>N<sub>y</sub> IMCs, six types of Pd<sub>1</sub>Cu<sub>3</sub>, Pd<sub>1</sub>Au<sub>1</sub>, Pd<sub>3</sub>Au<sub>1</sub>, Pd<sub>1</sub>Ag<sub>1</sub>, Pd<sub>1</sub>Zn<sub>1</sub> and Pd<sub>1</sub>In<sub>1</sub> IMCs catalysts can greatly improve C<sub>2</sub>H<sub>4</sub> formation activity and selectivity in comparison with that on Pd catalyst, since C<sub>2</sub>H<sub>4</sub> formation activity and selectivity on Pd<sub>1</sub>Au<sub>1</sub> is better than Pd<sub>3</sub>Au<sub>1</sub>, only Pd<sub>1</sub>Au<sub>1</sub> is considered. The results on five types of Pd<sub>1</sub>Zn<sub>1</sub>, Pd<sub>1</sub>In<sub>1</sub>, Pd<sub>1</sub>Ag<sub>1</sub>, Pd<sub>1</sub>Cu<sub>3</sub> and Pd<sub>1</sub>Au<sub>1</sub> catalysts (see Fig. S16) indicate that the route of C<sub>2</sub>H<sub>3</sub>+C<sub>2</sub>H<sub>3</sub> to produce 1,3-butadiene is the most advantageous on the Pd<sub>1</sub>Zn<sub>1</sub>, Pd<sub>1</sub>Cu<sub>3</sub>, Pd<sub>1</sub>Ag<sub>1</sub> and Pd<sub>1</sub>Au<sub>1</sub>, while the route of C<sub>2</sub>H<sub>2</sub>+C<sub>2</sub>H<sub>3</sub> is the most favorable on Pd<sub>1</sub>In<sub>1</sub>. Further, as shown in Fig. 7, the route of C<sub>2</sub>H<sub>3</sub>+C<sub>2</sub>H<sub>3</sub> to 1,3-butadiene is difficult in kinetics compared to C<sub>2</sub>H<sub>4</sub> desorption route on the Pd<sub>1</sub>Zn<sub>1</sub> (176.4 vs. 56.3 kJ·mol<sup>-1</sup>), Pd<sub>1</sub>In<sub>1</sub> (148.6 vs. 59.5 kJ·mol<sup>-1</sup>) and Pd<sub>1</sub>Cu<sub>3</sub> (61.9 vs. 46.2 kJ·mol<sup>-1</sup>); however, it is opposite on the Pd<sub>1</sub>Ag<sub>1</sub> (45.0 vs. 67.6 kJ·mol<sup>-1</sup>) and Pd<sub>1</sub>Au<sub>1</sub> (39.0 vs. 59.8 kJ·mol<sup>-1</sup>). Hence, green oil production can be inhibited on the Pd<sub>1</sub>Zn<sub>1</sub>, Pd<sub>1</sub>In<sub>1</sub> and Pd<sub>1</sub>Cu<sub>3</sub> IMCs catalysts.

Based on above results for Cu<sub>x</sub>M<sub>y</sub> or Pd<sub>x</sub>N<sub>y</sub> IMCs, it is obtained that compared to Pd catalyst, five types of Cu<sub>3</sub>Zn<sub>1</sub>, Cu<sub>3</sub>Pd<sub>1</sub>, Cu<sub>3</sub>Ag<sub>1</sub>, Pd<sub>1</sub>Zn<sub>1</sub> and Pd<sub>1</sub>In<sub>1</sub> IMCs catalysts not only possess better C<sub>2</sub>H<sub>4</sub> formation selectivity and activity, but also hinder green oil formation among the considered Cu<sub>x</sub>M<sub>y</sub> or Pd<sub>x</sub>N<sub>y</sub> IMCs catalysts.

### 3.4.3. The influences of partner metal ratio and type on H<sub>2</sub> dissociation

Since H<sub>2</sub> dissociation is the key step of C<sub>2</sub>H<sub>2</sub> selective hydrogenation, the adsorption and dissociation of H<sub>2</sub> on above five types of Cu<sub>x</sub>M<sub>y</sub> and Pd<sub>x</sub>N<sub>y</sub> IMCs including Cu<sub>3</sub>Zn<sub>1</sub>, Cu<sub>3</sub>Pd<sub>1</sub>, Cu<sub>3</sub>Ag<sub>1</sub>, Pd<sub>1</sub>Zn<sub>1</sub> and Pd<sub>1</sub>In<sub>1</sub> IMCs were further investigated (see Figs. S17 and S18), which have better C<sub>2</sub>H<sub>4</sub> formation activity and selectivity and the suppression ability toward the production of green oil compared to Pd catalyst. The results show that H<sub>2</sub> dissociative adsorption proceeds spontaneously on Cu<sub>3</sub>Pd<sub>1</sub>

Fig. 7. The overall barriers of the optimal route for 1,3-butadiene formation (red column) and C<sub>2</sub>H<sub>4</sub> formation (black column) in C<sub>2</sub>H<sub>2</sub> selective hydrogenation over the Cu<sub>3</sub>Zn<sub>1</sub>, Cu<sub>3</sub>Pd<sub>1</sub>, Cu<sub>3</sub>Ag<sub>1</sub>, Cu<sub>1</sub>Pt<sub>1</sub>, Cu<sub>3</sub>Ni<sub>1</sub>, Pd<sub>1</sub>Zn<sub>1</sub>, Pd<sub>1</sub>Ag<sub>1</sub>, Pd<sub>1</sub>Au<sub>1</sub> and Pd<sub>1</sub>In<sub>1</sub> IMCs. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

Fig. 8. The surface structures of (a)  $\text{Cu}_3\text{Pd}_1$ , (b)  $\text{Pd}_1\text{Zn}_1$  and (c)  $\text{Pd}_1\text{In}_1$  IMCs.

IMCs catalyst (see Fig. S17). However,  $\text{H}_2$  molecular adsorption occurs on the  $\text{Cu}_3\text{Zn}_1$ ,  $\text{Cu}_3\text{Ag}_1$ ,  $\text{Pd}_1\text{In}_1$  and  $\text{Pd}_1\text{Zn}_1$  IMCs, correspondingly,  $\text{H}_2$  dissociation barriers are 95.6, 113.5, 60.2 and 24.3  $\text{kJ}\cdot\text{mol}^{-1}$ , see Fig. S18, namely, the dissociation of  $\text{H}_2$  into H atom also easily occurs on the latter two IMCs. Therefore, three types of  $\text{Cu}_3\text{Pd}_1$ ,  $\text{Pd}_1\text{Zn}_1$  and  $\text{Pd}_1\text{In}_1$

IMCs catalysts can provide abundant hydrogen source to participate into  $\text{C}_2\text{H}_2$  hydrogenation, especially,  $\text{Cu}_3\text{Pd}_1$ . In addition,  $\text{H}_2$  dissociation is easy on the three-layer  $p(3 \times 3)$  (111) surface of  $\text{Cu}_3\text{Pd}_1$  IMCs [49]. Zhou *et al.* [20] experimentally and theoretically showed that PdZn IMCs promote  $\text{H}_2$  dissociation.

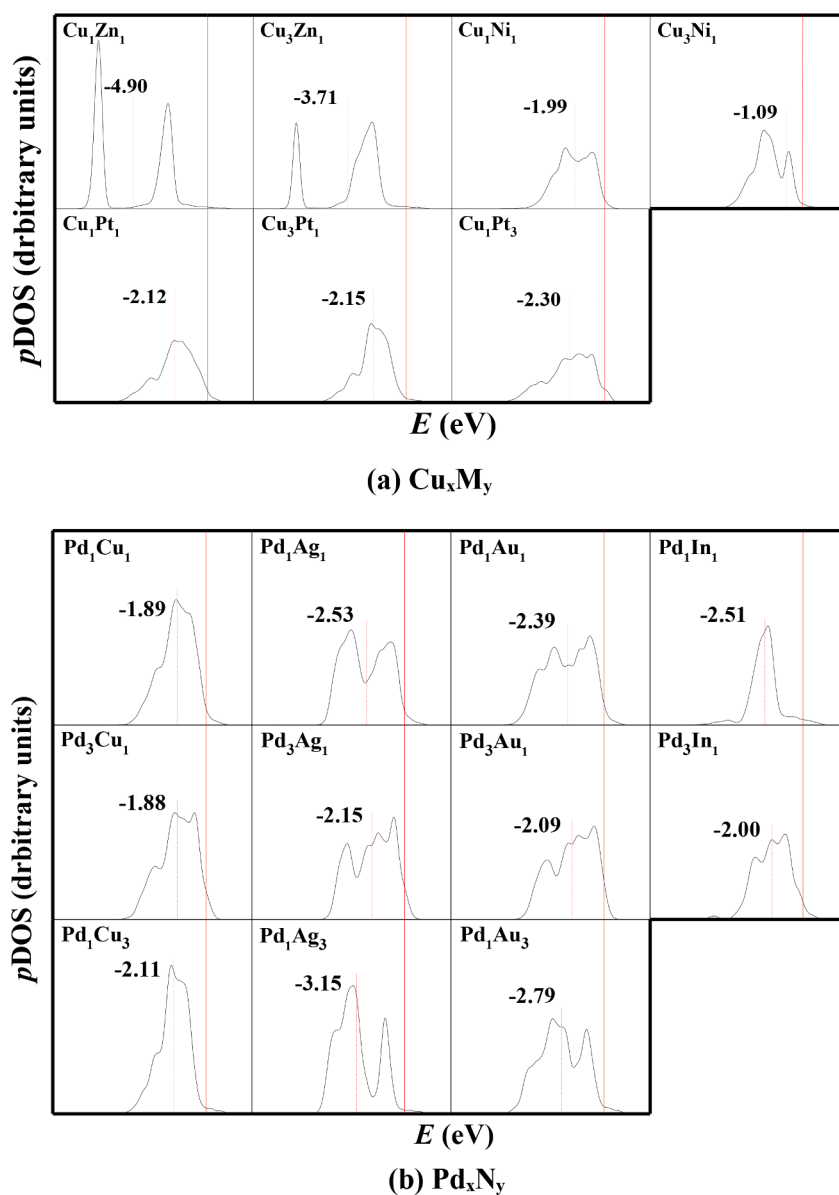

Fig. 9. Projected density of states (PDOS) plots for the  $d$ -orbitals of the outmost layer atoms over the (a)  $\text{Cu}_x\text{M}_y$  ( $M = \text{Zn, Pt and Ni}$ ) IMCs and (b)  $\text{Pd}_x\text{N}_y$  ( $N = \text{Cu, Ag, Au and In}$ ) IMCs. The dashed red lines represent the location of  $d$ -band center, and the solid red lines indicate Fermi energy level to be zero. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

**Fig. 10.** Comparisons of C<sub>2</sub>H<sub>4</sub> formation activity and selectivity between Cu<sub>3</sub>Pd<sub>1</sub> IMCs and other previously reported single-atom Pd catalysts: (a) Intermetallic compounds, (b) alloy surfaces, (c) the supported catalysts. The black bar stands for C<sub>2</sub>H<sub>4</sub> selectivity, and the red bar stands for the overall barrier of C<sub>2</sub>H<sub>4</sub> formation to reflect the activity, respectively. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

#### 3.4.4. The influences of partner metal ratio and type on surface structure

Taking C<sub>2</sub>H<sub>4</sub> formation activity and selectivity, the suppression of green oil and H<sub>2</sub> dissociation activity on the Cu<sub>x</sub>M<sub>y</sub> or Pd<sub>x</sub>N<sub>y</sub> IMCs into consideration, the surface structures for three types of Cu<sub>3</sub>Pd<sub>1</sub>, Pd<sub>1</sub>Zn<sub>1</sub> and Pd<sub>1</sub>In<sub>1</sub> IMCs with better performance are analyzed. As shown in Fig. 8, it is obtained that only three types of Pd<sub>1</sub>Zn<sub>1</sub>, Pd<sub>1</sub>In<sub>1</sub> and Cu<sub>3</sub>Pd<sub>1</sub> IMCs with the surface isolated single-atom Pd active centers can facilitate the reaction of C<sub>2</sub>H<sub>2</sub>+2H→C<sub>2</sub>H<sub>4</sub>. Meanwhile, the Pd<sub>1</sub>Ag<sub>3</sub>, Pd<sub>1</sub>Au<sub>3</sub> and Pd<sub>1</sub>Ga<sub>1</sub> IMCs also have the surface isolated single-atom Pd active centers, however, the close adsorption energies between C<sub>2</sub>H<sub>2</sub> and C<sub>2</sub>H<sub>4</sub> on the Pd<sub>1</sub>Ag<sub>3</sub> and Pd<sub>1</sub>Au<sub>3</sub> leads to poor catalytic performance, the low C<sub>2</sub>H<sub>4</sub> formation activity limits C<sub>2</sub>H<sub>4</sub> production on Pd<sub>1</sub>Ga<sub>1</sub>. Thus, different partner metal ratios and types alter surface structure of catalysts, and affect catalytic performance toward the reaction of C<sub>2</sub>H<sub>2</sub>+2H→C<sub>2</sub>H<sub>4</sub>. In addition, theoretical studies showed that PdCu<sub>3</sub> IMCs with three-layer model enables high C<sub>2</sub>H<sub>4</sub> formation activity and selectivity, and limits green oil production at 400 K [49]. Zhou *et al.* [20] experimentally and theoretically showed that PdZn IMCs is highly selective and active for C<sub>2</sub>H<sub>4</sub> formation, however, the green oil production is not considered. Feng *et al.* [6] experimentally and theoretically indicated that Pd<sub>1</sub>In<sub>1</sub> IMCs with the single-atom Pd active centers displays superior C<sub>2</sub>H<sub>4</sub> selectivity without considering green oil production.

Therefore, among all considered Cu<sub>x</sub>M<sub>y</sub> or Pd<sub>x</sub>N<sub>y</sub> IMCs catalysts in this study, Cu<sub>3</sub>Pd<sub>1</sub> IMCs with the surface isolated single-atom Pd active centers, namely, Pd<sub>1</sub>Cu<sub>3</sub> IMCs catalyst, is the best choice for C<sub>2</sub>H<sub>2</sub> selective hydrogenation, which not only exhibits high C<sub>2</sub>H<sub>4</sub> formation activity and selectivity, but also inhibits green oil production and provides abundant hydrogen source for C<sub>2</sub>H<sub>2</sub> selective hydrogenation. More importantly, Pd<sub>1</sub>Cu<sub>3</sub> IMCs reduces the use of precious metal Pd compared to the widely used Pd-based catalysts. In addition, the defective nanodiamond-graphene catalyst supported the single-atom Pd presents high C<sub>2</sub>H<sub>4</sub> selectivity [17]. Wei *et al.* [16] showed that the single-atom Pd fixed on the defects of nitrogen-doped carbon enables better C<sub>2</sub>H<sub>4</sub> formation activity and selectivity.

#### 3.4.5. The analysis of electronic properties

Aiming at further clarifying the roles of partner metal ratio and type in the Cu<sub>x</sub>M<sub>y</sub> and Pd<sub>x</sub>N<sub>y</sub> IMCs, the projected density of states for the *d*-orbitals of the outermost atoms of Cu<sub>x</sub>M<sub>y</sub> and Pd<sub>x</sub>N<sub>y</sub> IMCs facilitating C<sub>2</sub>H<sub>4</sub> formation are analyzed.

For the Cu<sub>x</sub>M<sub>y</sub> IMCs, Cu<sub>x</sub>M<sub>y</sub> (M = Zn, Pt and Ni) is considered, as presented in Fig. 9a, the distance between the *d*-band center and Fermi level follows the order: Cu<sub>3</sub>Zn<sub>1</sub> (-3.71 eV) < Cu<sub>1</sub>Zn<sub>1</sub> (-4.90 eV), Cu<sub>1</sub>Pt<sub>1</sub> (-2.12 eV) < Cu<sub>3</sub>Pt<sub>1</sub> (-2.15 eV) < Cu<sub>1</sub>Pt<sub>3</sub> (-2.30 eV) and Cu<sub>3</sub>Ni<sub>1</sub> (-1.09 eV) < Cu<sub>1</sub>Ni<sub>1</sub> (-1.99 eV), suggesting that Cu<sub>3</sub>Zn<sub>1</sub> catalyst with *d*-band center closer to Fermi level has superior activity than Cu<sub>1</sub>Zn<sub>1</sub>, the same things also occur on the Cu<sub>x</sub>Pt<sub>y</sub> and Cu<sub>x</sub>Ni<sub>y</sub> IMCs.

For the Pd<sub>x</sub>N<sub>y</sub> IMCs, as presented in Fig. 9b, Pd<sub>x</sub>N<sub>y</sub> (N = Ag, In, Cu and Au) is considered, the *d*-band center deviates the farthest from the Fermi level on the Pd<sub>1</sub>Ag<sub>3</sub> and Pd<sub>1</sub>Au<sub>3</sub> (-3.15 and -2.79 eV) catalysts without C<sub>2</sub>H<sub>4</sub> production. For Pd<sub>x</sub>In<sub>y</sub>, Pd<sub>1</sub>In<sub>1</sub> catalyst with *d*-band center far away from the Fermi level has superior catalytic activity than Pd<sub>3</sub>In<sub>1</sub> (-2.51 and -2.00 eV). The same things also occur on the Pd<sub>x</sub>Cu<sub>y</sub> with the order of Pd<sub>1</sub>Cu<sub>3</sub> (-2.11 eV) > Pd<sub>1</sub>Cu<sub>1</sub> (-1.89 eV) > Pd<sub>3</sub>Cu<sub>1</sub> (-1.88 eV), Pd<sub>x</sub>Ag<sub>y</sub> with the order of Pd<sub>1</sub>Ag<sub>1</sub> (-2.53 eV) > Pd<sub>3</sub>Ag<sub>1</sub> (-2.15 eV) and Pd<sub>x</sub>Au<sub>y</sub> with the order of Pd<sub>1</sub>Au<sub>1</sub> (-2.39 eV) > Pd<sub>3</sub>Au<sub>1</sub> (-2.09 eV), suggesting that Pd<sub>x</sub>N<sub>y</sub> (N = Ag, In, Cu and Au) with the *d*-band center far away from the Fermi level have better catalytic activity for C<sub>2</sub>H<sub>2</sub> selective hydrogenation. Zhao *et al.* [61] showed that Cu catalyst displays better C<sub>2</sub>H<sub>4</sub> formation activity with the *d*-band center far away from the Fermi level.

Above results show that the different partner metal ratios of Cu<sub>x</sub>M<sub>y</sub> (M = Zn, Pt and Ni) and Pd<sub>x</sub>N<sub>y</sub> (N = Ag, In, Cu and Au) IMCs can alter the location of *d*-band center, and further influence C<sub>2</sub>H<sub>4</sub> formation activity.

On the other hand, as presented in Section 3.4.4, taking C<sub>2</sub>H<sub>4</sub> formation activity and selectivity, the suppression of green oil and H<sub>2</sub> dissociation activity over the Cu<sub>x</sub>M<sub>y</sub> or Pd<sub>x</sub>N<sub>y</sub> into consideration, among them, three types of Cu<sub>3</sub>Pd<sub>1</sub>, Pd<sub>1</sub>Zn<sub>1</sub> and Pd<sub>1</sub>In<sub>1</sub> IMCs are the best choice for

$C_2H_2$  selective hydrogenation to  $C_2H_4$ , especially,  $Cu_3Pd_1$ ; Further,  $Cu_3Pd_1$  IMCs with the  $d$ -band center closer to the Fermi level possesses the highest  $C_2H_4$  formation activity. Thus, different partner metal types of  $Cu_xM_y$  or  $Pd_xN_y$  IMCs can also change the location of  $d$ -band center, and further influence  $C_2H_4$  formation activity.

### 3.4.6. Catalytic performance comparisons between $Cu_3Pd_1$ IMCs and the previously reported catalysts

In order to further explain outstanding selectivity and activity of  $Cu_3Pd_1$  IMCs with surface Pd single-atom, the comparisons about  $C_2H_4$  formation activity and selectivity between  $Cu_3Pd_1$  IMCs and previously reported catalysts were performed.

As presented in Fig. 10a, our results showed that on  $Cu_3Pd_1$ ,  $C_2H_4$  selectivity is  $122.3 \text{ kJ}\cdot\text{mol}^{-1}$ , and the activation barriers of  $C_2H_2+H\rightarrow C_2H_3$  and  $C_2H_3+H\rightarrow C_2H_4$  are  $51.0$  and  $46.2 \text{ kJ}\cdot\text{mol}^{-1}$ , respectively; the overall barrier of  $C_2H_2$  hydrogenation to  $C_2H_4$  is  $51.0 \text{ kJ}\cdot\text{mol}^{-1}$ .  $Pd_1Zn_1$  has  $C_2H_4$  selectivity ( $83.6 \text{ kJ}\cdot\text{mol}^{-1}$ ), and the activation barriers of  $C_2H_2+H\rightarrow C_2H_3$  and  $C_2H_3+H\rightarrow C_2H_4$  are  $102.0$  and  $56.3 \text{ kJ}\cdot\text{mol}^{-1}$ , respectively.  $Pd_1In_1$  corresponding to the surface single-atom Pd as the active centers displays high  $C_2H_4$  selectivity ( $217.0 \text{ kJ}\cdot\text{mol}^{-1}$ ), and the activation barriers of  $C_2H_2+H\rightarrow C_2H_3$  and  $C_2H_3+H\rightarrow C_2H_4$  are  $102.8$  and  $59.5 \text{ kJ}\cdot\text{mol}^{-1}$ , respectively. Thus, in this study, compared to  $Pd_1Zn_1$  and  $Pd_1In_1$ , the  $Cu_3Pd_1$  has higher  $C_2H_4$  formation activity and potential  $C_2H_4$  selectivity.

As presented in Fig. 10b, for the surface alloys doped by Pd single-atom, Zhang et al. [59,60] found that  $C_2H_4$  selectivity is  $42.6$  and  $36.4 \text{ kJ}\cdot\text{mol}^{-1}$  on the  $PdCu(111)$  and  $PdCu(211)$  doped by Pd single-atom, respectively; the overall barriers of  $C_2H_2$  hydrogenation to  $C_2H_4$  are  $47.5$  and  $78.8 \text{ kJ}\cdot\text{mol}^{-1}$ , respectively. However, ethane formation is easy on Pd-doped  $Cu_2O(111)$ . In addition, ethane is easily formed on the single-atom Pd-doped  $Cu_{13}$ ,  $Cu_{38}$  or  $Cu_{55}$  clusters in  $C_2H_2$  selective hydrogenation [70].  $C_2H_4$  is easily over-hydrogenated to generate ethane on the  $PdAg(111)$  doped by Pd single-atom [71] and  $Pd_1M@Pd(111)$  ( $M = Cu, Au$  and  $Ag$ ) [8]. Hence, the alloy surfaces doped by Pd single-atom as reported above still present lower  $C_2H_4$  formation activity and selectivity compared to  $Cu_3Pd_1$  in this study.

As presented in Fig. 10c,  $C_2H_4$  selectivity over the stable catalyst with Pd single-atom fixed on the defects of nitrogen-doped carbon is  $91.0 \text{ kJ}\cdot\text{mol}^{-1}$ , and the overall barrier of  $C_2H_2+2H\rightarrow C_2H_4$  is  $94.0 \text{ kJ}\cdot\text{mol}^{-1}$  [16]. The catalyst with Pd single-atom dispersed onto the defective nanodiamond-graphene has  $C_2H_4$  selectivity of  $51.0 \text{ kJ}\cdot\text{mol}^{-1}$ , and the overall barriers of  $C_2H_2+2H\rightarrow C_2H_4$  is  $110.0 \text{ kJ}\cdot\text{mol}^{-1}$  [17]. The catalyst with the atom-dispersed Pd onto nitrogen-doped graphene has  $C_2H_4$  selectivity of  $88.0 \text{ kJ}\cdot\text{mol}^{-1}$  [72].  $Pd_1/SVG$  catalyst with Pd single-atom supported by a single vacancy graphene facilitates ethane formation [73]. Interestingly,  $Pd_1/GDY$  catalyst with Pd single-atom supported on the graphdiyne presents significantly high  $C_2H_4$  selectivity ( $261.4 \text{ kJ}\cdot\text{mol}^{-1}$ ) with the overall barriers of  $38.4 \text{ kJ}\cdot\text{mol}^{-1}$  for  $C_2H_4$  formation [73]. As a result, except for  $Pd_1/GDY$  catalyst, the other supported single-atom Pd catalysts mentioned above still exhibit lower activity and selectivity toward  $C_2H_4$  formation compared to  $Cu_3Pd_1$  IMCs in this study. Moreover, although  $Pd_1/GDY$  catalyst presents better  $C_2H_4$  selectivity and formation activity than  $Cu_3Pd_1$  IMCs,  $Cu_3Pd_1$  IMCs with ordered atomic arrangement and structural characteristics presents stronger thermal stability than the single-atom  $Pd_1/GDY$  catalyst.

Thus, the  $Cu_3Pd_1$  or  $Pd_1Cu_3$  may become a promising catalyst in  $C_2H_2$  selective hydrogenation, which not only presents the industrially practical  $C_2H_4$  formation activity and selectivity, but also possesses outstanding thermal stability.

## 4. Conclusions

In this work, aiming at reveal the most suitable partner metal type and ratio among the  $Cu_xM_y$  and  $Pd_xN_y$  IMCs and further screen out the most suitable IMCs with excellent catalytic performance for  $C_2H_2$  selective hydrogenation, density functional theory calculations were performed to systematically investigate the underlying mechanism of  $C_2H_2$

selective hydrogenation on the different types of  $Cu_xM_y$  ( $M = Zn, Pt, Ni, Pd, Au$  and  $Ag$ ) or  $Pd_xN_y$  ( $N = Zn, Ga, In, Sn, Cu, Ag$  and  $Au$ ) IMCs catalyst. This study examined the influences of the partner metal ratio and type in the  $Cu_xM_y$  and  $Pd_xN_y$  IMCs on the four key factors of  $C_2H_2$  selective hydrogenation, including  $C_2H_4$  formation activity and selectivity, green oil production and  $H_2$  dissociation activity. Taking above four factors into account, the results reveal that either  $Cu_3Pd_1$  or  $Pd_1Cu_3$  IMCs with the surface isolated single-atom Pd anchored into IMCs bulk performed as active centers should be the most suitable intermetallic compound among the  $Cu_xM_y$  and  $Pd_xN_y$  IMCs, which presents the industrially practical performance for  $C_2H_4$  formation in comparison with the previously reported single-atom Pd catalysts in experimental and theoretical studies. The excellent performance of  $Cu_3Pd_1$  IMCs catalyst for  $C_2H_4$  formation is attributed to the unique surface structures and electronic properties. Meanwhile, compared to the widely used Pd-based catalysts, the  $Cu_3Pd_1$  or  $Pd_1Cu_3$  IMCs with the surface isolated single-atom Pd catalyst not only reduces the cost of catalysts with the non-noble metal Cu as the main body, but also maximizes the utilization of noble metal Pd. This study provides valuable information for the design and screening out of intermetallic compound catalysts in selective hydrogenation of alkynes.
